In the early part of 1653, both the republics addressed their chief attention to the preparation of their fleets. Blake was enabled to muster sixty sail, with which he attempted to intercept a large convoy of merchant ships, protected by Van Tromp's more numerous, if not more weighty force. On the 18th of February the two contending fleets met, when there ensued an obstinate and bloody conflict, which lasted three days, at the end of which Van Tromp retreated with the loss of eleven ships. The English had lost but one, but the whole fleet was so shattered that they could not pursue. The loss in killed and wounded was nearly equal on both sides; and though the English gained the victory, Van Tromp, by his excellent seamanship, was enabled to convey in safety to the Dutch ports the numerous trading vessels which he had been sent to protect.

At this period Sweden discovered a disposition to join her fleets to those of England, but the diplomatic skill of the Dutch ambassador prevailed on her to agree to a neutrality; and the king of Denmark made a treaty, stipulating to furnish to the Dutch a fleet of twenty sail, to confiscate the English ships in the port of Copenhagen, and to exclude all English vessels from trading in the Baltic. The Danish ships never joined, but the treaty enabled the Dutch to obtain supplies of timber and other stores. Though secret negotiations for peace had been entertained between Cromwell, now master of England, and De Witt, recently appointed pensionary of Holland, yet, as they terminated in nothing, the most extraordinary preparations were made to continue the conflict. In the beginning of June, Van Tromp, seconded by De Witt and De Ruyter, appeared on the ocean with a fleet of ninety-eight men of war and seven fire-ships. They were speedily met by an English fleet of ninety-five sail and five fire-ships, commanded by Blake, Monk, and Dean. On the 2d of June an obstinate battle took place, which speedily terminated in favour of the English. The victory was complete. Three of the best Dutch ships were sunk, two blown up, eleven captured, with many merchantmen; and the whole of them would have been destroyed, but for their timely retreat to the shoals, where the larger English ships could not follow them. The English did not lose a single ship, but Admiral Dean, one captain, and some few inferior officers and seamen, were killed. Van Tromp attributed his defeat to the inferiority of his ships in size and in weight of metal, and to the want of sufficient ammunition, especially gunpowder.

In consequence of this disaster, the party opposed to the house of Orange raised a cry in favour of peace, and some secret negotiations were carried on with Cromwell; but the public voice was strongly in favour of the Orange party, and compelled the government to renew the naval war. Another fleet superior in numbers was hastily prepared, and ready to proceed to sea in the middle of July. This last fleet amounted to one hundred and twenty sail, and they proceeded as soon as collected to engage the fleet of England, commanded by Monk, Lawson, and Penn, between Scheveling and the mouth of the Meuse. But Tromp fell early in the action, and his death had a bad effect. A rout followed, and the Dutch lost twenty-six ships, with 4000 men killed, and near 2000 prisoners. The English lost some ships, had 600 men killed and 1000 wounded; but their ships had been so severely shattered that they were immediately obliged to seek repairs in their own ports.

The Dutch, though defeated, were not dispirited, and prepared to renew the contest, unless Cromwell would abandon his proposition for the annihilation of the power of the Orange family. He however had determined on a war with Spain, and on expeditions to Spanish America. He withdrew his propositions respecting the house of Orange, but obtained others excluding the royal family of England and their adherents from all refuge within the states, and thus a peace was concluded. The states of Holland bound themselves to exclude the house of Orange from the stadtholderate, but the other states did not agree to it; some of the members even of that province protested against the exclusion, and it was highly unpopular with the great body of the citizens everywhere but in Amsterdam.

The war with England, though short in its duration, had been very expensive as well as sanguinary. It was however no sooner at an end than the Dutch were engaged in hostilities with the Portuguese respecting their settlements in Brazil, which were terminated without any decisive naval combat. But many of the ships of Portugal were captured; and De Ruyter was sent with a fleet to make demonstrations before Lisbon, but having encountered severe storms, his ships were so much damaged that he was compelled to return to repair them, and soon afterwards peace was concluded.

The Dutch next interfered in a contest between the Danes and the Swedes. The latter power had besieged Copenhagen, when the Dutch admiral Opdam was despatched to the Baltic for its relief. He attacked and defeated the Swedish fleet under the walls of Cronenburg, and, by the supplies given to the Danes, saved their capital. A peace was soon afterwards concluded between the northern powers, through the mediation of Holland and England.

The death of Cromwell, in September 1658, had a favourable effect on the Orange party in the United Provinces, whilst the restoration of Charles to the throne of England strengthened it still more; and, though Holland opposed it, a settlement of a large sum was voted to support the household, and carry on the education of the prince. This became necessary from the French king having, upon some very frivolous pretences, seized on the principality of Orange. Charles and his adherents were full of animosity towards the Dutch; and they, elated with their independence, and their powerful naval forces, were not disposed to yield to the indignant superiority which the restored monarch had assumed. The Louvestein faction had again, under De Witt, reared its head in Holland, and some efforts were made to form a union with France, with the view of making a conquest of the ten Netherland provinces, and dividing them between France and Holland. By this proceeding, suspicions and jealousies were created towards the states, on the part of all the other governments of Europe. Towards England the Dutch had shown some animosity, and held language the more presumptuous because their party in England, the remains of the Cromwell faction, had assured them that, from the want of money, Charles would be unable to go to war. To the dismay of the Louvestein party in Holland, the king resolved on hostilities; and in April 1665, his parliament having voted abundant supplies, a fleet under the command of the Duke of York issued forth, and, after the capture of some merchant ships, finding no enemy, returned to Harwich. The states of Holland and Zealand with great activity prepared a naval force of 120 sail of vessels. The commander, Opdam, was met on the 1st of June by the Duke of York with 100 sail, and, after some manœuvring during two days, a battle was fought, in which the English were victorious, chiefly, as the Louvestein party affirmed, from the treachery of some of the captains of the Dutch ships. Their admiral was blown up in his flag-ship; the second in command, Cartemaer, was wounded, and died a prisoner; and eighteen ships, with 6000 men, were captured. The loss of the English was but one ship, and that of men on board the duke's ship was 200: the rest of the fleet had suffered very slightly; but Admiral Lawson, one of the most brave and skilful of the English commanders, fell in the conflict.

The remains of the Dutch fleet made a skilful retreat, and great vigour was exerted to reinforce it. The plague at that time raged in London, and prevented equal exertions from being made, so that the Dutch were enabled early in the following year to assemble a force of eighty-three large ships, furnished with much heavier metal than they had before employed. This force was greater than any that the English could oppose to it. A part too of the English fleet had been despatched to cruise in the mouth of the Channel, by which the grand fleet under the Duke of Albemarle was rendered still more inferior to that of the enemy. The Dutch were commanded by De Ruyter, and the opposing fleets met, and engaged on the 1st of June. The contest continued with great vigour throughout the day; but a reinforcement of sixteen ships having joined De Ruyter, Albemarle drew off, but being pursued, he turned on the enemy, and renewed the battle. During this fight the English Channel fleet made its appearance under Prince Rupert. The contest continued, on the whole, four days. The English then retreated in good order, with the loss of twenty-two ships. The Dutch had lost only seven ships, and were enabled to keep the sea, thus claiming the victory, and even threatening a descent on England.

The English fleet was so quickly reinforced, that on the 24th of July it again appeared at sea, and once more encountered the enemy with success. Three of the Dutch admirals and twelve captains were killed, with 2000 men; and seven ships were sunk, but none taken. After this last battle the English had the command of the sea, and inflicted a severe retaliation for the losses and mortifications they had endured. This produced great exhibitions of party-spirit in Holland, and also disposed them to peace. England, by the extravagance of its sovereign, by the sufferings of the plague and of the fire of London, and the intrigues of France, was much in need of peace.

Conferences were accordingly opened at Breda; but King Charles, with the negligence which characterised his government, had not stipulated for a cessation of hostilities during the negotiations. De Witt took advantage of this, and despatched a fleet to the Thames, which advanced to the Medway, and thus closed for a short time the port of London, at the same time threatening the naval arsenal of Chatham. This in its issue was little more than a bravado, though, after retreating from the Thames, the Dutch made some valuable captures. The negotiations at Breda were however carried on, and peace finally concluded on the 10th of July 1667.

This treaty was followed by one between England, Sweden, and Holland, designed to oppose the growing power of France. The king of England, at that time a pensioner, as well as some of his ministers, on the court of France, behaved with the greatest duplicity, and, upon the most frivolous pretences, resolved to aid France in her projects to conquer the whole of the Netherlands. Under pretence of supporting the triple alliance, Charles obtained money from his parliament, and then determined to attack the Dutch commercial fleets, which were navigating the ocean in full security in the state of peace which had been established. A rich fleet from the Mediterranean was expected to arrive in 1672, when Admiral Holmes was sent with a naval squadron to intercept it. Holmes assumed a pacific behaviour, but the Dutch distrusted him. He made an attack on the fleet, and took one of the ships of war and three small merchant vessels; but the rest, fighting as they retreated, reached the ports of Holland in safety. This naturally produced a declaration of war; and France, joined with England, was engaged in a contest, the object of which was to conquer the whole of the Low Countries, and subject them to the dominion of France.

The violent party-spirit in Holland was ground of alarm. The jealousy of the house of Orange had induced the party of De Witt to neglect the land forces, and the army was in a state of indiscipline, and especially in want of skilful officers, as nearly all the more experienced men of that profession were adherents of the house of Orange, and on that account were not employed. The naval force was in a far better state under the immediate control of the Louvestein faction, though many of its commanders were of the Orange party. De Ruyter was enabled speedily to fit out a fleet of ninety-one ships of war and forty-four fire-ships, and with them sailed to attack the fleet of England and France. This combined force, under the Duke of York and Marshal d'Etrées, was at anchor in Solebay on the coast of Suffolk, where the Dutch hoped by the help of their fire-ships to achieve their destruction. But the united fleets either cut or slipt their cables, and fought the Dutch on the open sea. The fight was tremendous, and was only ended by darkness, when the Dutch withdrew to their own ports. The loss on both sides was nearly equal, but heaviest on the English ships, as their new allies took but little share in the action. It was supposed they had secret orders to spare their own ships, whilst the Dutch and English should weaken each other, a supposition confirmed by subsequent events.

In the mean time the army of France had begun to act on the land side, under Louis XIV., who himself took the field. It was the most numerous and best appointed which Europe had ever seen. It amounted to 120,000 men, including the auxiliary troops of the elector of Cologne and of the bishop of Munster. The Dutch had not more than 25,000 to take the field, and the elector of Brandenburg had engaged to furnish an equal number, on the condition that the Dutch navy should assist him in taking Pomerania from the Swedes. The internal state of Holland was disturbed by party-spirit, but neither party were disposed to submit to a foreign dominion. The partisans of De Witt had projected a flight by sea, and made some preparations for the transport of 50,000 families to Batavia. The young Prince of Orange, though of a sickly frame, resolutely encouraged a spirit of defence, hopeless as it appeared; and when asked what he should do if the French should conquer the country, gallantly replied, "die in the last ditch." This inspirited others, and by the universal voice he was declared stadtholder with unlimited power, and the De Witts were prosecuted, stripped of their wealth, sentenced to perpetual banishment, and murdered by the populace.

In the mean time the French had made a rapid progress, and, proceeding by the Rhine, had subdued the provinces of Utrecht, Guelderland, and Overyssel. Amsterdam, Rotterdam, the Hague, with Middleburg, and the islands, were reduced to great straits, but were held by the Prince of Orange. As a last resource, the patriotic resolution was taken to drown the country, with its invaders. By this step, when the sluices were opened, the French were in part drowned, and such diseases broke out in their army that Amsterdam was saved. Louis had made more than 24,000 prisoners. These he could no longer keep, and on their release they joined their countrymen. The spirit shown by the Dutch had excited an interest in their favour with the emperor of Germany and other princes of the empire, and even the Spanish governor of the Netherlands sent to their aid a force of 10,000 men. A diversion too was operated in behalf of the Dutch by the elector of Brandenburg, and, though impeded by the French general Turenne, it proved of some benefit to the states.

Charles, though somewhat dissatisfied with the French, sent an English fleet to act in combination with that of France, and conquered the province of Zealand; but contrary winds rendered the attempt unsuccessful. In the beginning of 1673, an attempt was made by a French division under the Duke of Luxembourg, to march over the ice and seize Amsterdam and the Hague; but this attempt failed with great loss to the invaders, owing chiefly to a sudden thaw. In the same year a combined English and French fleet, the former commanded by Prince Rupert, and the latter by D'Etrées, engaged the Dutch fleet under De Ruyter and Van Tromp. After much cannonading, in which the French were accused of backwardness, the conflicting navies returned to their ports, each of them claiming a victory. This occurred on the 14th of June.

By this time Spain had declared war against France, the Imperialists had advanced, the invading army was compelled to abandon its conquests in Holland as rapidly as it had gained them, and the dominions of the elector of Cologne, the ally of France, including the city of that name, and Bonn, were occupied by the allies and the armies of Holland.

These events led to negotiations under the mediation of Sweden, and in 1674 a peace was concluded between all the belligerent powers. The transactions of the negotiators were so managed by the address of the Prince of Orange, as to enable him to lay the foundation of the grand alliance, by which, in subsequent periods, after his accession to the English throne, the power of Louis XIV. was reduced to the lowest point.

In 1677 the Prince of Orange was married to the Princess Mary, daughter of the Duke of York, and niece to Charles; an event hailed as favourable to their interests by the Dutch, and by those in England who were unfavourable to the mean dependence on the French court, to which Charles' pecuniary wants had subjected him.

The Dutch sent a fleet under De Ruyter to join that of Spain in the Mediterranean. In a contest with the French De Ruyter was mortally wounded, though his fleet was victorious; but in a subsequent battle the Dutch and Spaniards were defeated with great loss, by which the French became masters of the Mediterranean.

The Prince of Orange had attained to supreme, almost to absolute power in Holland. His ruling principle was hostility to France, arising from the manifest ambition of Louis XIV. With this impression he was induced to direct all his efforts to counteract the influence of France, especially amongst the German states. As his father-in-law James, who had ascended the English throne, was acting in an opposite direction, to the great disgust of the leading Protestants of his dominions, the prince opposed him by maintaining a correspondence with the discontented. They were received by him with some degree of privacy; but as James proceeded in his measures against the established religion, they became too numerous to escape the notice of France, though they engaged but little share of the attention of James, probably from the deceit of one of his ministers, who has been accused by history of having acted a false part towards him. A jealousy existed, though with no great force on the part of James, towards France, and this induced him to decline the acceptance of offers of succour from Louis XIV.

The Prince of Orange, under the pretext of a dispute with Bavaria and the elector of Cologne, collected an army of 14,000, with transports sufficient to convey them to England. After being once driven back by storms, the forces landed in Torbay on the 4th of November 1688; and thus was effected that change of succession usually called the Revolution, the details and consequences of which belong more to the history of England than to that of Holland.

The change of sovereigns brought England into the grand alliance against France; and the united navies, in 1692, fought the battle of La Hogue, in which, after a contest of three days' continuance, the French admiral Tourville was completely beaten, and suffered the loss of sixteen of his largest ships. The Dutch commerce suffered considerably by the privateers of France, especially by the operations of the celebrated Du Bart; but these and other hostilities were suspended by the peace of Ryswick, concluded in 1697.

The death of King William occurred in 1701, just at the commencement of that war respecting the Spanish succession, which continued till the peace of Utrecht, in the year 1712. The transactions connected with it belong more to the history of other countries than to that of Holland, though the Dutch states under the succession of William, who was created stadtholder, continued to bear a considerable share in the contests.

About the year 1742 the Louvestein party had gained the upper hand in Holland; and Cardinal Fleury, the French minister, engaged the states in some intrigues, and even hostilities, upon which a stadtholder was again appointed, and soon afterwards a general peace was concluded, that of Aix-la-Chapelle, in 1748.

The prince stadtholder died in 1751. He had seen but little service in the field, yet he had proved himself an active and skilful chief of the republic. He left a son and daughter, both minors; and his office was intrusted, as well as the education of his children, to their mother, a daughter of George II.

Whilst the Seven Years' War raged, from 1758 to 1763, Holland maintained its neutrality, or at least affected to do so. Great complaints and many discussions arose with England, on a question of neutral rights, which has continued till the present time; but they led to no events of any importance. When the war between England and her American colonies broke out, the question of neutral rights was again resumed; but, in the midst of the discussions on that subject, it was discovered that an attempt at a treaty with those called by us our rebel subjects had been favourably received in Amsterdam, and Mr Laurens, an American ambassador on his passage, was captured with the correspondence. This led to hostilities, in which St Eustatia in the West Indies was taken by the English. In the year 1782 a Dutch fleet was equipped, and met on the Dogger Bank by an English fleet of nearly equal force under Admiral Parker. A bloody fight ensued, which terminated in favour of the English. The peace which followed, in 1783, restored tranquillity to Holland, which had suffered severe losses by captures during the short hostilities that had been carried on. After the peace, the Anti-Orange party in Holland, which, from the hereditary dignity having been conferred on that family, had appeared extinct, gained fresh influence, and again raised its head. The Princess of Orange, the sister of the king of Prussia, had been grossly insulted, upon which that monarch demanded satisfaction, and this being refused, he marched an army into Holland, which was feebly defended by the clamorous boasters of their bravery. Amsterdam was occupied by the Prussians in September 1787; the stadtholder was reinstated in the power of which he had been deprived; and a strict alliance was formed with England and Prussia. Though tranquillity was thus restored, the party which had been suppressed were dissatisfied, and watched for the fittest opportunity to avenge their mortifications.

Nor was it long before an occasion presented itself. In 1794, when the French republican flag was displayed on the frontiers, the defeated party were active and clamorous, and when the country was invaded by the army of Pichegru, they gave it every assistance in their power. This state of affairs, with a frost of great intensity, which admitted the passage on the ice of the artillery and heavy baggage of the French army, rendered the conquest of Holland of easy accomplishment. In 1795 the Orange family fled and took refuge in England, whilst a republican constitution, framed by the French faction of the day, was established, with a directory of five persons as the executive power. The new republic, called the Batavian, was compelled to cede to France some parts of its territory, with the cities of Maestricht and Venlo, and the province of Limburg. An immediate demand was enforced for the payment of ten millions sterling, and the army of France was to be paid, fed, and clothed at the expense of the Batavian republic. Under this state of things, one part of their navy was given up to the British by the dissatisfied seamen, another part fought and were defeated; their colonies surrendered or were taken by the same power, their commerce was confined to mere coasting, and the bank of Amsterdam nearly shattered; but not a fraction of the pecuniary demands was abated by their new allies.

The constitution was new-modelled in 1801. The number of the directors was diminished, a kind of upper house was created in imitation of the council of ancients in France, and the country was divided into eight departments. The peace of Amiens gave back to Holland their colonies in South America and the Cape of Good Hope, but left Ceylon in the hands of England. When the war was renewed, the restored colonies were again captured, their ports were strictly blockaded, and every hope of prosperity was extinguished. In April 1805 a new constitution was introduced by France, and Schimmelpenninck was made sole director; but his integrity was unable to serve his country in the difficult circumstances in which both he and it were placed. It was therefore determined by Bonaparte to create Holland into a separate kingdom, and place his brother Louis on the throne. This was executed in June 1806. On his accession Louis availed himself of the talents and integrity of the late director, and acted, as far as he was able, for the benefit of the people over whom he had been placed as sovereign. But none of his efforts proved effectual in removing the general distress, and even in the few which were made, he was so controlled by his imperial brother, that, without communicating his intention, Louis withdrew himself from Holland, renounced all authority, and, with but scanty means of subsistence, took up his residence as a private individual in the dominions of the emperor of Austria. This step has been represented as having been hastened by his incapacity to relieve the distress which had been produced in his dominions by the landing of the English in Middleburg in their attempt upon Antwerp in 1809.

Louis retired in July 1810, and Holland was by a decree of the emperor incorporated as an integral part of his empire; Amsterdam was declared to be the third city of the imperial dominions; the French conscription law was extended to the whole of Holland, and those taken under it were equally divided between the land and the sea service; and the country was then, for military purposes, formed into two divisions.

Under this military yoke the Dutch suffered till after the battle of Leipsic in October 1813, when a part of the victorious army under General Bulow advanced toward Holland, and met there an English division under General Graham. On the 20th of November the two commanders called on the Dutch to join the cause of the allies. Two days before this, Count Hogendorp, a moderate Orangist, had privately collected in his house a number of the most distinguished persons, who, like himself, had formed part of the ministry from 1788 to 1795, and persuaded them to take upon themselves the provisional government, till the Prince of Orange, who was expected from England, should arrive.

A correspondence was opened with General Bulow, and with the allied monarchs, who had advanced to Frankfort; and invitations were addressed to the prince, who with little delay arrived at the Hague, and proceeded to Amsterdam amidst the rapturous acclamations of the assembled crowds. Proclamations had been circulated generally, headed, "The Netherlands are free, and William I. is the sovereign prince of this land of liberty." He however refused to assume any power till an assembly could be convened, which might properly be considered as a fair representation of the whole people. An assembly of notables, consisting of the most distinguished men of all parties and professions, was speedily called together. The number summoned was 600; of these, 125 declined attending, some on account of their age, others from ill health or personal reasons. With the dissent of only twenty-six voices, the prince was declared king, and a constitution decreed, which secured to him considerable power, limited, however, by two legislative assemblies.

When the French forces were compelled to abandon the ten ancient provinces of the house of Austria, these were considered as conquests made by the allied powers, who assumed the disposal of them. The congress of Vienna, of which Austria, the former sovereign of those provinces, was a member, resolved that they should be united with the seven provinces, and form together one independent kingdom, under a constitution, of which the princes of the house of Orange were to be hereditary monarchs. As an indemnification to the prince, now king, for the loss of his states in Germany, the duchy of Luxembourg, with the exception of the fortress, was given up to be added to this newly-constructed kingdom, and in it was included the ancient bishopric of Liège.

Before the complicated arrangements which the union of these parts required could be completed, the return of Bonaparte from Elba, and the revolt of the French army, created impediments to the settlement of internal affairs. But this newly-constructed kingdom, which was the first object of attack, entered with energy into the contest, and their troops, mustered as they had hastily been, took an honourable part, under the eldest son of the king, now Prince of Orange, in the grand events of that short but brilliant campaign of 1815, which ended in the decisive victory of Waterloo.

The consolidation of such heterogeneous bodies as the inhabitants of Belgium and those of Holland was a difficult task, owing to their differences of religion, of laws, of language, and of occupations. The Belgians were rigid Catholics, and their clergy strove to prevent the toleration of all other professions; their laws had all been founded on the system of the ancient Dukes of Burgundy, but altered to suit the Code Napoleon. The language spoken by the major part of the people, though it nearly resembled the Dutch, had considerably varied from it in the practice of two hundred years; and besides, a numerous portion of them spoke French almost exclusively, whilst another portion spoke the Walloon, and in Luxembourg the German language predominated. The Dutch were principally conversant in trade, in the fisheries, and in manufactures, whilst the Belgians were chiefly employed in agriculture.

The members of the legislative body contained nearly an equal division of the two countries; and as they acted rather with the feeling of delegates from the parts by which they were chosen, than as the representatives of the interests of the whole community, their decisions were subject to great fluctuations, according to the number of Dutch or of Belgian members who might happen, by sickness or by accident, to be prevented from being present when the votes on a particular proposition were taken. This inconvenience might have been removed by time, if other causes had not been in operation. The agriculturists wished to monopolise the whole supply of corn by means of a restrictive law; but the distillers, who used a great quantity of Baltic corn in making gin, and the speculative merchants in grain, who were a medium for supplying that commodity to a great extent from countries in which it was cheap, to countries in which it was dear, claimed a continuance of the free trade which they had long enjoyed. Though this point was finally settled in favour of the Dutch party, it caused a rankling feeling in the minds of the Belgians. The assemblies, besides their ordinary occupations, had their attention constantly directed to the composition of a system of law, applicable both to civil and to criminal cases, and had made great progress in the work. After much opposition to religious toleration, in which the king displayed both temper and firmness, a concordat was made with the pope, which, if not quite satisfactory, would, if left to itself, have probably removed all existing obstacles. The difference of language, though represented by those who availed themselves of every pretext to produce mischief, as of importance, was not in reality of very great moment. The Belgic and the Dutch are scarcely more dissimilar than the English and the Scotch, and one or the other was the language of a vast majority. All the books of any value were in the Dutch dialect, but they were neglected by the Belgians, of whom the few that could and did read drew their ideas from French publications. By directing all law proceedings to be carried on in the vernacular languages, a body of impetuous young men, imbued with French principles, were inflamed against the government, and gained more influence than they could have obtained if the exclusion of the French tongue from the courts had been gradually and not suddenly attempted.

In spite of these obstacles to a more perfect union, no country ever made so rapid a progress in prosperity as was exhibited in Belgium. The products of its soil, the iron and the coals of Liège and of Luxembourg, found most beneficial markets in Holland. The corn was, in spite of that imported from the north of Europe, sold at profitable rates. The trade with the Dutch colonies being opened to them, and the valuable port of Antwerp being no longer closed, Belgium made a great progress in foreign trade. The effect of this was to create new manufacturing establishments of cotton, woollen, and linen goods, and to extend those which had before existed. The advancement of the country was manifested to the most casual observer, and seen in the increase of private and public buildings, and in the improvement and embellishment of the old ones, in every city, town, and village.

The state of ease and improvement so striking in Belgium was, however, no security against the union of opposite factions, who agreed in nothing but in the work of inflaming the worst passions of the most ignorant part of the community, who, though highly bigoted to their religion, were made tools to overturn the government, by those who avowedly hated it.

The Parisian revolution of July 1830 quickly produced a similar one in Brussels. The events passed as rapidly as in the former city. There were few or no troops, a negligent and inefficient police force, and no spirit amongst those who possessed property, to protect it against the plunderers. They prayed the king to send troops to protect them; but when these arrived, the inflamed Belgians, who were from policy mixed up in the same ranks with the Dutch, would not act, and they abandoned the city. The mob, thus triumphant, compelled the feebler but richer citizens to submit to their demagogue leaders. This produced a declaration of independence against the house of Orange.

In the mean time, the Dutch, who were not without causes of complaint of the greater favour shown to the Belgians than to themselves, were firm in their allegiance to the monarch, and wished for a separation of the two countries. This measure was proposed and discussed in the legislative assembly at the Hague, and ultimately, by a majority, but not a large one, determined upon.

Application was made by the king of the Netherlands, to the several powers who had at Vienna sanctioned the union, and guaranteed to him the possession of his throne. This led to discussions and negotiations, during which a monarch was elected by the Belgians. They wished one from the family of Napoleon, or that of Orleans, but were not allowed a free choice, and at length Prince Leopold of Saxe-Coburg was placed on the throne.

The Dutch soon composed an army, which, though inferior in number to that of Belgium, invaded the country. The Belgians displayed neither courage nor discipline, but fled in all directions; and their new king would, but for an accident, have been made prisoner. A division of the French army advanced to the aid of the Belgians, upon which the Dutch retired.

The citadel which commanded the city of Antwerp was still garrisoned by a Dutch force. It appeared proper to England and France that this should be given up to Leopold; and as the Dutch refused to surrender it till all other subjects of contest between the two countries were arranged, it was resolved to compel its surrender by warlike measures. The ports of Holland were blockaded, and the fortress of Antwerp was attacked by a French army, and, after a gallant defence, compelled to capitulate. The embargo was then taken off, and all hostilities ceased in 1833.

The king still retains his former title of king of the Netherlands, but as that will probably be finally changed for some other of a more definite nature, we here confine our statistical description to the country actually under his authority, the divisions, extent, and population of which are as follow:

Provinces.	Extent in Acres.	Population.	Cities.	Market Towns.	Villages.
North Brabant	1,283,200	349,289	16	11	143
Guelderland...	1,310,700	312,897	22	3	381
North Holland	573,300	417,458	14	4	212
South Holland	713,300	484,608	18	4	281
Zealand.........	415,600	137,194	20	2	308
Utrecht.........	341,250	131,835	6	1	107
Friesland	682,500	207,425	11	1	336
Overyssel.......	827,000	180,495	16	3	198
Groningen	579,300	159,321	4	0	280
Drenthe.........	614,500	64,028	1	2	37
	7,340,600	2,444,550	128	31	2283

In this account the duchy of Luxembourg is omitted, as being at present the subject of negotiation between Belgium and Holland, in which are also intermingled the views of the powers who were parties to the treaty of Vienna, as well as those of the Germanic confederation.

That province extends over 2193 square miles, contains twenty-two cities and towns, and 809 villages, with 302,654 inhabitants. A part of it, however, comprehending the strong fortress of the same name, with a circle of four leagues around, will be continued in the hands of the German confederation, whether the remaining part should form a part of Holland or of Belgium.

The cities of Holland containing each more than 10,000 inhabitants, with their actual population, were in 1833 as in the statement subjoined.

Cities.	Population.	Cities.	Population.
Amsterdam	202,364	Hague	56,105
Rotterdam	72,294	Utrecht	43,407

Cities.	Population.	Cities.	Population.
Leyden	34,564	Middleburg	14,700
Groningen	30,260	Arnhem	14,509
Haarlem	21,667	Deventer	13,639
Leuwarden	20,938	Breda	13,114
Bois-le-Duc	20,489	Gouda	12,878
Dort	19,972	Amersfort	11,782
Nimeguen	17,734	Tilbourg	11,726
Zwolle	15,640	Scheidam	11,588
Delft	15,023	Zutphen	10,204

The proportion of the town population to that of the villages is far greater than is to be found in any other part of the world, as appears by the following table.

Comparison of the Town with the Rural Inhabitants of Holland.

Provinces.	Town Population.			Country Population.		
	Males.	Females.	Total.	Males.	Females.	Total.
North Brabant	35,399	35,550	70,946	137,791	140,151	277,942
Guelderland	39,807	42,668	82,475	115,502	111,816	227,318
North Holland	125,282	150,656	275,941	68,882	69,165	138,047
South Holland	116,211	137,101	253,312	112,956	113,466	226,425
Zealand	20,025	23,120	43,145	47,034	47,083	94,117
Utrecht	30,690	34,035	64,725	34,258	33,376	67,634
Friesland	25,084	28,229	53,383	75,867	75,659	151,526
Overyssel	18,552	19,609	38,161	71,921	68,813	140,734
Groningen	14,119	16,141	30,260	63,505	63,739	127,244
Drenthe	5,254	5,278	10,553	27,274	26,062	53,336
	430,423	492,387	922,901	754,990	749,330	1,504,323

It is worthy of remark, that whilst in the country inhabitants the males rather exceed the females, in the cities and towns the females exceed in number the males by nearly a fifteenth part.

Provinces.	Varieties of Religious Sects.				
	Protestants.	Catholics.	Jews.	Unknown Sects.	Total.
North Brabant	41,840	305,446	1,476	129	348,891
Guelderland	188,319	118,003	2,748	723	309,793
North Holland	274,211	114,705	24,117	955	413,988
South Holland	353,852	117,364	7,596	925	479,737
Zealand	100,747	36,060	454	1	137,262
Utrecht	77,490	53,340	1,484	45	132,359
Friesland	184,787	18,543	1,555	24	204,909
Overyssel	117,131	59,362	2,231	171	178,895
Groningen	143,198	11,646	2,660	......	157,504
Drenthe	60,173	2,451	1,172	72	63,868
	1,541,748	836,920	45,493	3,045	2,427,206

The several sects are maintained by the government, although some particular churches have endowments. The greater part of the Protestants are of the Calvinistic profession. The Lutherans are the next in number, the Menonites and the Remonstrants exceed 120,000, but the whole of the other Protestants taken together are not more than half the number of the Calvinists. By the budget of 1833 the sums voted for the support of the Protestant worship amounted to 1,330,000 florins (L.115,000), and for the Catholic worship 400,000 florins (L.33,400), besides the expense of the universities. There are now three universities, viz. Leyden with 684 students, Utrecht with 476, and Groningen with 284. These are indiscriminately resorted to by the different religious parties, whose separate theological studies are provided for by the state under professors of each faith.

The uncertain state of the external relations, and especially of those with their late fellow subjects, has caused an augmentation of the forces both by land and by sea, far beyond what can be needed or supported for a long period. The regular land army, which is well organized and disciplined, consists of forty-eight battalions of infantry, twenty-three squadrons of cavalry, nine corps of riflemen, and a proportional force of artillery. Besides these troops, a numerous body of volunteers, called the Schuttery, are in a state of preparation to act in the defence of the country. The navy consists of eight ships of the line, two of eighty-four guns and six of seventy-four. The frigates are three of sixty guns, thirteen of forty-four guns, and seven of thirty-two guns. There are fourteen corvettes mounting from twenty to twenty-eight guns, and sixteen brigs from eight to eighteen guns, and several armed steam-vessels have been recently constructed. For the defence of the internal water frontier, there are about eighty large gun-boats or barks armed, each of them having a twenty-four pound gun at their prow, two six pounders at the stern, and two carronades on the sides. This force is manned with 7000 good seamen, independently of officers, and is peculiarly appropriate for defence.

The finances of the kingdom are at present in a provisional state, owing to the indecisive negotiations which have been for several years under discussion, respecting the division of the national debt, which belonged to the two countries of Belgium and Holland when united as one kingdom. The plan decided on by the allied powers, and acquiesced in by both governments, was, that this debt should be divided into thirteen parts, of which seven should be assumed by Belgium and six by Holland. But as Belgium pays no part of the interest, the dividends have hitherto been regularly discharged by Holland. The credit of that government is good, and the wealth of its subjects abundant, and the king finds no difficulty whatever in availing himself of both during the uncertain period, which is still protracted. The expenses were thus estimated for the year 1833:

Civil list	1,425,000 florins.
Secretaries of state	572,840
Department of foreign affairs	596,200
…………… of the interior	3,103,309
Department of justice	1,150,000 florins.
…………… of worship	1,730,000
Naval force	6,500,000
Army	12,100,000
National industry and colonies	587,016
Interest on the debt	21,621,484
	49,385,849

As twelve florins are equal to a pound sterling, the whole ordinary expenditure consequently amounts to L.4,115,480; but to this must be added 44,000,000 florins for extraordinaries on account of warlike preparations. If tranquillity be restored, and Belgium should pay her proportion of the interest on the debt, the finances of this kingdom will be in a prosperous state. During the union, the Belgic portion paid taxes at the rate of ten florins per head on the whole population, whilst Holland paid rather more than fifteen florins per head. With only its due proportion of the debt, Holland would have a surplus revenue for its ordinary expenses, and might reduce annually a portion of its debt, especially as she has the whole of the colonial possessions, and the far greater proportion of the shipping, the fisheries, and the foreign trade.

The foreign possessions of Holland are the following:

		Whole Inhabitants.	Whites.	Free Coloured.	Slaves.
Asia	Batavia	4,800,700	50,000	4,758,300	12,400
	Amboyna	45,000	400	44,000	600
	Banda	44,000	400	43,000	600
	Ternate	170,000	300	169,500	200
	Macassar	360,000	500	358,500	1000
	Sumatra	1,040,000	500	1,038,500	1000
	Timor	85,700	600	84,000	400
Africa	Forts on the coast of Guinea, with only garrisons.				
America	Surinam	57,040	6,050	7,100	74,500
	St Eustatia	13,710			
	Curaçoa	12,350			
	St Martin's	4,100			
	Saba	450			

Besides these, the Dutch claim the islands of Oruba and Orubilla, that of Bonaire or Buenos Ayres, with the Bird Islands; all near the coast of the late Spanish settlements. They have few or no resident inhabitants, but a few persons occasionally repair to them to take turtles or to collect salt.

The government of Holland is a monarchy, hereditary in the house of Orange, and limited, by the constitution founded in August 1815, to the power of executing the laws. It was grounded on the ancient habits and usages, only making the executive power permanent, instead of occasional and temporary, as it was when a stadtholder was formerly appointed. The legislature is composed of two houses. The lower house has fifty-five members, none of whom can be less than forty years of age, and of these twenty-two are chosen by the provinces of North and South Holland, seven by North Brabant, six by Guelderland, five by Friesland, four each by Overyssel and Groningen, three each by Zealand and Utrecht, and one by Drenthe. The upper house consists of the nobles, appointed for life by the king.

As the greater part of the establishments of the country are permanent as well as ancient, and as the greater part of the revenue is voted every ten years in anticipation, the transactions of the chambers occupy but a short space of time, nor do they create so great an interest as in countries where more business is brought under the notice of the popular assemblies. In this kingdom the far greater part of their internal affairs are settled in the provincial assemblies of the several states, and in corporate bodies of the larger cities; all of whom have considerable funds under their control, and exercise extensive power within their respective limits.

From the economical habits of all classes, of which the monarch is an eminent example, the expenses of the several public functionaries are fixed upon a very moderate scale. This habit of prudence and foresight has descended from the higher to all other classes of society, and has been the main cause of that great accumulation of wealth, which, from the foundation of its independence, and in spite of the severe reverses it has sustained, has made this kingdom so remarkable.

No observant traveller can pass through Holland without feeling surprise at the abundant wealth, and the profitable application of it to the obtaining of additional wealth, which is everywhere to be seen. This is manifested in the public and the private buildings, in the farming erections, in the boundaries of the land, in the dykes, the canals, the roads, the mills for keeping the fields clear of water, in the wheel carriages, and in the cattle, as well in those applicable to labour, as in those kept for the dairy or for food. The same may be seen in what relates to their ships, boats, workshops, and the interior of the dwellings. All are distinguished by their cleanliness and order, which, the Dutch have by long experience known, are essential ingredients of economy.

During the twenty years from 1794 to 1814, when the country was subjected to France, when the foreign trade was annihilated, and the intercourse with the colonies was suspended, it has been estimated that more than one hundred millions sterling, beyond the expenses of government, were extorted from Holland by their acute masters. This is said to have been encountered by such rigid parsimony, practised by all individuals and families, that the actual capital of the country was little, if at all, impaired by the extortion it had endured. On the return of tranquillity, the capital thus reserved was in a great degree employed in loans to the several foreign states of Europe; which loans were made on terms so advantageous to the lenders, that, between 1814 and 1833, more gain has been made by the Dutch capitalists than had been taken from them in the preceding twenty years.

This traffic in money, of which Amsterdam may be considered as the central market for the whole of Europe, is not confined to the great capitalists, as in most other countries, but by various modes is so diffused over the community, that those who have but small reserve funds are enabled to partake of the advantages of it, and that whilst pursuing their regular and customary occupations.

With the return of peace the intercourse had been renewed with the colonies in the East Indies, and upon the coast of South America, which had been restored in an improved condition. This gave rise to a profitable commerce with the south-eastern part of Asia, and enabled the proprietors of estates in Surinam to realize their property. The transit trade, the fisheries, the commerce with the Baltic, and with the kingdoms of Spain and Portugal, and the ports of the Mediterranean, were all re-opened, and extended beyond their former limits. During the continuance of the union with Belgium that part of the kingdom shared these branches of profit, chiefly through the noble port of Antwerp. But the late revolutionary events have nearly thrown the whole of that commerce into the hands of the Dutch. As the most substantial of the merchants and the larger ship-owners have removed from Antwerp to Rotterdam or Amsterdam, it is probable that the trade of Holland, whatever may be the result of the pending negotiations, will be benefited by the separation of the two countries.

During the war, especially after the Berlin and Milan decrees, much of the inert capital of Holland was directed towards the improvement of the soil and cultivation, and its fruits in a few years vastly increased. Many of these now form an important portion of its export trade. Those here enumerated have been doubled in quantity in the ten years up to the time of the insurrection at Brussels; and the exports annually, on an average of three years ending with 1829, were as follow:—

Butter	7,924,778	pounds.
Cheese	16,383,217	...
Oilcakes	15,024,579	...
Oil from rape and linseed	019,260	hogsheads.
Salted meat	355,860	pounds.
Hams	136,312	...
Hemp, rape, and linseed	196,800	bushels.

Another product of the soil, the export of which is of vast extent, but not very accurately ascertained, is gin, distilled from corn in the large establishments in the city of Scheidam, and some other places. It is not, however, the sole product of their own soil, as much of the corn from which it is made is previously imported from the Baltic, and other northern ports of Europe. This corn trade was once a very extensive branch, but of late years, from causes too complicated to be explained here, it has been very much contracted, and the large storehouses of Amsterdam have been but slightly furnished with it.

The favourable situation for commerce in which Holland is placed, at the mouths of great rivers, besides the facilities for defence, has induced the construction of works which, though chiefly intended for protection, are beneficial as means of intercourse. The artificial canals are numerous and extensive, and have been constructed at an expense which only the general economy could have encountered. Without enumerating them, one of recent construction deserves especial notice. The ship canal from the Helder to Amsterdam, which was completed and opened in 1825, is about eighty miles in length, 120 feet broad, and twenty-five feet deep; thus capable of conveying into the capital the largest ship of war. It is an undertaking, both by its execution and its cost, worthy of the most flourishing period of the republic. The expense of the work has exceeded one million sterling.

During the union of Belgium with Holland, the former country had extended its manufacturing industry, and, from being more favourably situated, had prevented Holland from re-establishing those fabrics of woollen and linen goods which had flourished before the occupation of the country by the French. At present the manufactures of Holland are upon a narrow scale. Some linen, with a few woollen and cotton goods, are made, but chiefly for domestic consumption. A few articles of tapes and other small wares are made at Haarlem; and some linens are still bleached there, which are either made in the country, or imported in an unbleached state from Silesia. The business of refining sugar is carried on extensively in Amsterdam, and that of making snuff and tobacco gives occupation to numerous labourers. The making of gin has been already noticed, to which it may be added, that the breweries are large and numerous. The building of ships, barges, and boats, is now the chief branch of manufacturing industry; and in the beauty of their form, in their durability, and in their adaptation for stowage, the builders of Holland have of late years been making a rapid progress. The greatest deficiency in Holland is the want of occupation for common labourers; for although in the season of harvest there is not a sufficiency of hands for the work of the field, and thousands from Westphalia repair to it to gather in the crops, yet at other seasons the distress is very great, and in no country is there so much call for the practice of benevolence as in Holland, and nowhere such abundant exercise of that virtue.

The fisheries on their own coasts, as well as those on the shores of Great Britain, employ many seamen, as does the Greenland whale-fishery; but this is chiefly a summer labour, and that class of workmen feel much distress in the winter, especially whenever, as is a common occurrence, the canals are frozen, and cease to be navigable.

The agriculture of Holland is well conducted, with very productive results in the lower parts of the country. Wheat is but little cultivated, rye is more extensively so; but the most profitable grain is oats, of which alone more is exported than is imported. Barley is but little grown, and what is needed is chiefly supplied from Germany by the inland rivers. In the recently-cultivated poor lands in Groningen and Drenthe much buck-wheat is grown. Potatoes also are abundantly produced. The more beneficial products are those from the cattle, such as butter, cheese, bacon, and hams; and on the farms where they are maintained are raised the greater part of those seeds from which their oil is made.

The climate is moist, and the soil generally damp; and in winter, especially in Amsterdam and some other cities, the fogs are extremely dense. These circumstances, combined with a scarcity of good water to drink, are considered as the causes of the increase of population being slower in Holland than in any other country of the European continent. The mode of living may have some effect on longevity: though the people are warmly clothed, yet the use of stoves, in which turf is burned, must be injurious in the manner there practised. The great quantity of cured fish, bacon, and butter, used as food, and the abundant drinking of ardent spirits, stimulated by the smoking and chewing of tobacco, must contribute in some degree to shorten the lives of the inhabitants.

The language of Holland is a dialect of the high German, derived from it when less improved than it has been within the last century. It first assumed a decided character in the latter end of the fifteenth century, and has from that time to the present been receiving additional polish from the literary labours of the several distinguished men who have cultivated it, from Agricola and Erasmus, down to the time of the lately deceased Bilderdyk. It would probably have been much further improved if some of its most distinguished authors, such as Erasmus, Lipsius, Grotius, Wyttenbach, and others, had not, for the sake of greater circulation, written in the Latin language. Though the Dutch prose has but little pretension to elegance in its tones and its expressions, it is well calculated to convey clear ideas, and to explain useful truths with great simplicity and accuracy.

In no country of Europe has the proportion of highly learned men to the whole population been so great as in Holland. The earliest impulse to literature was communicated by William the first Prince of Orange, who founded the University of Leyden in 1575, as a reward to that city for its brave defence against the Spaniards in the preceding year. Men like Scaliger, Lipsius, Heinsius, Gronovius, and Spanheim, in ancient learning; Erpenius and Gollius in oriental literature; Arminius, Drusius, and Coccejus, in theology; and the two Snelliuses, in mathematics, extended their own fame, and that of their university, throughout the whole of Europe. Soon afterwards, the high schools of Franeker, of Groningen, and of Utrecht, produced a rivalry highly advantageous to the diffusion of knowledge.

Towards the end of the seventeenth century, Huygens Leeuwenhoeck, Zwammerdam, and Hartseeker, were highly distinguished as astronomers and as natural historians. After the peace of Utrecht in 1713, Albert Schultens, Hemsterhuis, and the celebrated Boerhaave, with a long list of others, began to extend the study of the Greek and of the oriental languages, to improve their own, and more especially to diffuse a more correct knowledge of the healing art. The science of the law of nations, as well as of law in general, owes much to eminent Dutch writers; and nowhere has the research into antiquities been more assiduously pursued, or with greater success. The celebrity of Dutch literature invited able men from other countries, and their works published in Holland still further extended the renown of the Dutch schools. Thus Scaliger and Luzac were of French origin; Albinus, Vossius, Gronovius, Ruhnken, and Vorstius, were Germans; and Wyttenbach was a native of Switzerland. In history, in criticism, and in poetry, the Dutch were behind no other people; and, considering the paucity of readers of their language, their progress and excellence is astonishing. It would be easy to give a list of dramatic and other poetical authors of high merit, but whose talent cannot be appreciated beyond the limits of their own confined territory.

Amidst their fierce contests, and their eager desire of gain, the fine arts, especially painting, had numerous patrons in Holland, and produced artists who powerfully, but in a peculiar manner, rivalled those of Flanders and of Italy. The Dutch school of painting has been praised for the truth of its representation of natural objects, for its perfect finishing, its appropriate shading, and the colouring and delicacy of pencil; but it has been censured for its selection of unworthy objects, and want of correctness in drawing. The founder of the school was Lucas of Leyden, born in the year 1494. His most eminent followers were, Van Been of Leyden, born in 1586, said to have been an instructor of Rubens; Bloemart of Gorcum, who painted historical pieces, landscapes, and cattle, and died in 1647; Cornelius Poelenburg of Utrecht, born in 1586, and died in 1663, who was peculiarly happy in his landscapes with figures, and his two distinguished pupils Bertange and Haensberge; also Rembrandt, who, by his exquisite skill in colouring, was enabled to hide all his other faults. Without enumerating their peculiarities, and without extending the list, we insert the following names, most of which are well known to those who have paid any attention to the history of painting and painters. Zachtleben, Gerhard Terburg, Swanvelt, Asselyn, Gerhard Dow, Peter Van Leer, Wouverman, Waterloo, Berghem, Paul Potter, Backhuysen, Mieris, Schalken, Jardin, Ruysdael, Van der Werf, and Van Hulst. To these, others of second-rate merit might be added. It is singular, that with their great skill in painting, the Dutch have made an indifferent figure in the sister art of statuary. In architectural taste also they have been deficient, but that has made some progress of late years, as may be observed in the buildings of more modern erection.

In the mechanical arts the Dutch have attained a high degree of perfection, as far as these are connected with their peculiar situation. In the conducting of water, and in the formation of dykes, bridges, sluices, and canals, their skill and contrivances to facilitate labour are obvious to all travellers who visit the country; and they excel all other nations in the construction of their mills, and in whatever pertains to the making of wheels, either for mills or for waggons and coaches. In such works, as indeed in all others, they exhibit the highest degree of neatness, strength, and economy.

The works chiefly referred to in this article are, *Histoire des Troubles des Pays-Bas*, par Vander Vynckt, 3 vols. edition 1822; *Analecta Belgica de Hoynck de Papendrecht*, 1743; *Histoire de la Guerre des Pays-Bas*, par Strada, 1604; *Geschichte des Abfalls der Niederlands von der Spanische Regeirung* von Schiller, edit. 1829; *Geographie Historique, Physique, et Statistique, du Royaume des Pays-Bas* (Amsterdam, 1827), par J. J. de Cloet; *Jaarbokje over* 1831, 1832, 1833, von Z. M. Koning in Gravenhage; *Almanach der* 1834, Weimar.

HOLLAND, New, the largest island in the world, reaching from 10° to 40° south latitude, and between 114° and 153° of east longitude from London. See the article Australasia for a general account of this immense island; and the article Wales, *New South*, for an account of the British Penal Colony established in it.

Holland, in commerce, a fine and close kind of linen, so called from its being first manufactured in Holland.

HOLLAR, Wenceslaus, a celebrated engraver, born at Prague in 1607. His parents were respectable, and he was at first designed for the study of the law. But the civil commotions which happened in his youth having ruined his family affairs, he was obliged to shift for himself; and discovering some genius for the arts, he was placed with Marian, an able designer and engraver of views. Being himself a man of great ingenuity, he profited largely from the instruction of his tutor. He principally excelled in drawing geometrical and perspective views, and plans of buildings ancient and modern, also landscapes, and every kind of natural and artificial curiosities, which he executed with a pen, in a style well adapted to the purpose. He travelled through part of Germany; but notwithstanding his merit, he met with so little encouragement that he found it difficult to support himself. The Earl of Arundel being in Germany, took him under his protection, brought him to England, and recommended him to the favour of Charles I. He engraved a variety of plates from the Arundel collection, and the portrait of the earl himself upon horseback. The civil wars which broke out soon afterwards in England ruined his fortune. He was taken prisoner with some of the royal party, and escaped with difficulty; upon which he returned to Antwerp, and joined his old patron the Earl of Arundel. He settled in that city for a time, and published a considerable number of plates; but his patron having soon afterwards proceeded to Italy for the benefit of his health, Hollar fell again into distress, and was obliged to work for the printsellers and booksellers of Antwerp at very low prices. At the Restoration he returned to England, where, though he had sufficient employment, the prices he received for his engravings were so inadequate to the labour necessarily required, that he could barely procure a subsistence; and the plague, with the succeeding fire of London, having for some time put an effectual stop to business, his affairs were so much embarrassed that he was never afterwards able to improve his fortune. It is said that he used to work for the booksellers at the rate of fourpence an hour, and always had an hour-glass before him. But all his industry, to which his numerous works bear ample testimony, failed to procure him a sufficient maintenance. On the verge of his seventieth year he was attached with an execution at his lodgings in Gardener's Lane, Westminster, when he desired only the liberty of dying in his bed, and that he might not be removed to any other prison than the grave, a favour which it is uncertain whether or not he obtained. He died in 1677. According to Vertue's Catalogue, his works amount to nearly twenty-four thousand prints, and the lovers of art are always zealous to collect them. Generally speaking, they are etchings performed almost entirely with the point. Their merits are thus characterized by Mr Strutt: "They possess great spirit, with astonishing freedom and lightness, especially when we consider how highly he has finished some of them. His views of abbeys, churches, ruins, &c. with his shells, muffs, and every species of still life, are admirable; his landscapes frequently have great merit; and his distant views of towns and cities are not only executed in a very accurate, but a very pleasing manner." But a somewhat colder character is given of them by Mr Gilpin in his essay on prints: "Hollar gives us views of particular places, which he copies with great truth, unornamented, as he found them. If we are satisfied with exact representations, we have them nowhere better than in Hollar's works; but if we expect pictures, we must seek them elsewhere. Hollar was an antiquarian and a draughtsman, but seems to have been but little acquainted with the principles of painting. Stiffness is his characteristic, and a painful exactness void of taste. His larger views are mere plans. In some of his smaller, at the expense of infinite pains, something of an effect is sometimes produced. But in general we consider him as a repository of curiosities, a record of antiquated dresses, abolished ceremonies, and edifices now in ruins."

HOLLOA, in nautical language, an exclamation of answer, to any person who calls to another to ask some question, or to give a particular order. It is also the answer in hailing a ship at a distance.

HOLM (Saxon, Hulmus, *insula amnica*), denotes an isle or fenny ground, according to Bede, or a river island. And where any place is called by that name, and this syllable is joined with any other in the names of places, it signifies a place surrounded with water, as the Flatholmes and Stepholmes in the Severn near Bristol; but if the situation of the place be not near the water, it may then signify a hilly place, *holm* in Saxon signifying also a hill or cliff.

HOLMS, two islands in the Bristol Channel, distinguished by the appellation of the flat and the steep, which form part of the Welsh county of Glamorgan. On the former is a light-house, and a dwelling for those who superintend the lights, and a few other houses, with about fifty acres of cultivated land. The latter is a rock about 400 feet in height, with a difficult and dangerous access. The soil is sandy, and the vegetation confined, and only fit for rabbits, of whom great numbers are found there.

HOLOCAUST (formed from ὁλος, *whole*, and καιω, *to consume with fire*), a kind of sacrifice, in which the whole offering is burned or consumed by fire, as an acknowledgment that God, the creator, preserver, and lord of all, was worthy of all honour and worship, and as a token of men's giving themselves entirely up to him. It is also called in Scripture a *burnt-offering*. Sacrifices of this sort are often mentioned by the heathens as well as Jews (Xenophon, *Cyropæd.* lib. viii. p. 446, 1738), and they appear to have been in use long before the institution of the other Jewish sacrifices by the law of Moses (Job, i. 5, xli. 8; and Gen. viii. 20, xxii. 13). On this account the Jews, who would not allow the Gentiles to offer on their altar any sacrifices peculiarly enjoined by the law of Moses, permitted them by means of the Jewish priests to offer holocausts, because these were a sort of sacrifices prior to the law, and common to all nations. During their subjection to the Romans it was no uncommon thing for the Gentiles to offer sacrifices to the God of Israel at Jerusalem. Holocausts were deemed by the Jews the most excellent of all their sacrifices. It is said that this kind of sacrifice was in common use amongst the heathens, till Prometheus introduced the custom of burning only a part, and reserving the remainder for his own use.

HOLOFERNES, lieutenant-general of the armies of Nebuchadonosor, king of Assyria, who having in a remarkable encounter overcome Arphaxad, king of the Medes, sent to all the neighbouring nations with an intention of obliging them to submit to his empire, pretending that there was no power capable of resisting him. At the same time Holofernes, at the head of a powerful army, passed the Euphrates, entered Cilicia and Syria, and subdued almost all the people of these provinces.

Being resolved to make a conquest of Egypt, he advanced towards Judæa, little expecting to meet with any resistance from the Jews. In the mean time, he was informed that they were preparing to oppose him; and

Achior, the commander of the Ammonites, who had already submitted to Holofernes, and joined his army with some auxiliary troops, represented to him that the Hebrews were a people protected in a particular manner by Almighty God, as long as they were obedient to him; and therefore that he should not flatter himself with expectations of overcoming them, unless they had committed some offence against God, and thereby become unworthy of his protection. Holofernes, disregarding this advice, commanded Achior to be conveyed within sight of the walls of Bethulia, tied to a tree, and left there; but the Jews came thither and unbound him.

In the mean time Holofernes formed the siege of Bethulia; and having cut off the water which supplied the city, and set guards at the only fountain which the besieged had near the walls, the inhabitants were soon reduced to extremity, and resolved to surrender if God did not send them succour in five days. Judith, informed of their resolution, conceived the design of killing Holofernes in his tent. She took her finest clothes, went out of Bethulia with her maid-servant, and being brought to the general, pretended that she could no longer endure the sins and excesses of the Jews, and that God had inspired her with the design of surrendering herself to him. As soon as Holofernes saw her, he was taken with her beauty, and some days afterwards invited her to a great feast which he had prepared for the principal officers of his army. But he drank so much wine, that drunkenness, and its immediate consequence, sleep, prevented him from satisfying his passion. Judith, who in the night was left alone in his tent, cut off his head with his own sword, and departing with her servant from the camp, returned to Bethulia with the head of Holofernes. As soon as it was day, the besieged made a sally upon their enemies, who going into their general's tent, found his headless carcass besmeared with its own blood. They then discerned that Judith had deceived them, and fled with precipitation, leaving the camp abounding with rich spoils. The Jews pursued them, killed a great number, and returned loaded with booty.

There is a considerable diversity of opinion as to the time when this war between Holofernes and the Jews happened. Some date it from the captivity of Babylon, in the reign of Manasseh, and pontificate of Eliakim the high priest; others place it some time after the captivity; and some doubt the truth of the whole transaction.

HOLOGRAPHUM (composed of ὁλος, *all*, and γραφω, *I write*), in the civil law, something written wholly in the hand-writing of the person who signs it. The word is chiefly used in speaking of a testament written wholly in the testator's own hand.

HOLSTEIN, a province of the kingdom of Denmark, one of those by which the king becomes a member of the Germanic confederacy. It was an ancient duchy, and the termination of the ancient German empire, from the year 811 till its dissolution. It is bounded on the north by Sleswick, from which it is separated by the river Eider and the Sleswick Canal; on the north-east and east by the Baltic Sea; on the south-east by the territory of Lubeck and the duchy of Lauenburg; on the south by the Elbe and the state of Hamburg; and on the west by the German Ocean. The province extends over 3260 square miles, and comprehends fourteen cities, twenty-two market-towns, 141 parishes, with 486 villages, and 374,750 inhabitants. The population are of the Saxon race, and speak the common platt Deutch, but the educated portion of the people speak the German language; their speech, as well as their manners and customs, seem to have borrowed little from the Danes, though they have for many centuries been a part of the same kingdom.

The soil is upon the whole fruitful; for though, in the centre of the province, there is a long strip of poor sand, scarcely worth cultivation, yet on both sides the land is highly productive. The western side, especially near the shore, consists of some of the best meadow-land in Europe, on which are fattened those fine oxen the meat of which is known by the name Hamburg beef, and much of it is exported from that city, as well as from Altona. When, in the course of husbandry, these lands are broken up, they produce abundant crops of oats, and some very tolerable wheat. On the eastern side, upon the Baltic, is much excellent arable land, and tolerably well managed, yielding the best of butter, with some wheat and barley; but the principal corn grown is rye. It may be said of Holstein, that it is the best agricultural district in the north of Germany. The climate is, however, cold, raw, and changeable, which is injurious to its rural husbandry.

The trade of the province is considerable. On every part of the coasts of both seas the fisheries afford much occupation. The number of ships belonging to the several ports of Altona, Kiel, Flensburg, and Gluckstadt, creates and employs many most valuable seamen. The chief trade consists of the export of corn, butter, cheese, bacon, cured fish, rape-seed, honey, and wax. The Greenland fishery is carried on from Altona. The import trade chiefly arises from the Danish colonies in the West Indies, the produce of which is brought to Altona or Flensburg.

The manufactures are of small amount, excepting that of building and equipping ships. There are some small establishments for making paper, cutlery, copper articles, and common ironmongery. The shores of the Baltic present very picturesque scenes, from the deep indentations of the sea (called *fiorde*) into the land, where they spread out and resemble lakes, and are bordered by woods rising gradually to the tops of the hills. From the eastern side of this country, in the district of Engeland, according to tradition, Hengist and Horsa, two of the princes, sailed on their expedition to our island.

HOLT, SIR JOHN, Lord Chief-Justice of the Court of King's Bench in the reign of King William, eldest son of Sir Thomas Holt, serjeant-at-law, was born at Thame, Oxfordshire, in 1642. He entered himself at Gray's Inn in 1658, and applied to the common law with so much industry that he soon became an eminent barrister. In the reign of James II. he was made recorder of London, an office which he discharged with much approbation for about a year and a half; but he lost his place by refusing to expound the law suitably to the king's designs. On the arrival of the Prince of Orange he was chosen a member of the Convention Parliament, which afforded an opportunity of displaying his abilities; and as soon as the government was settled, he was made Lord Chief Justice of the Court of King's Bench and a privy counsellor. In 1700, when Lord Somers resigned the great seal, King William pressed Chief-Justice Holt to accept of it; but he replied that he never had in his life but one chancery cause, which he lost, and that consequently he could not think himself qualified for so great a trust. He continued as chief justice for twenty-two years, during which time he obtained great reputation for steadiness, integrity, and thorough knowledge in his profession. Upon great occasions he asserted the law with intrepidity, though he thereby ventured to incur by turns the indignation of both houses of parliament. Holt was a perfect master of the common law, and as his judgment was sound, his capacity great, and his understanding clear, so he possessed a firmness of mind, and a vigour of resolution, which nothing could overcome when he found himself called upon to assert the authority of the law, and to vindicate the purity of justice. Several causes of the utmost importance, as affecting the lives, rights, liberties, and property of the people, came in judgment before him, and his decisions were all marked by the same high qualities. His definitions were remarkable for clearness and perspicuity; his arguments displayed equal powers of analysis and arrangement; and he possessed the invaluable faculty of rendering perceptible and obvious the natural differences of things, at the same time that he discriminated, with the nicest tact, between real and fanciful resemblances. His great secret consisted in the rigid and scrupulous adjustment of his premises; and hence he seldom erred in his conclusions. His arguments were instructive and convincing, whilst his integrity shrunk from any accommodation of judicial opinion to existing interests or prejudices. His decisions are, most of them, faithfully and judiciously reported by Chief-Justice Raymond, himself an eminent lawyer; and his integrity and uprightness as a judge are celebrated by the author of the *Tatler* (No. 14), under the character of Verus the magistrate. The following reports were published by him, in 1708, folio, with notes: "A Report of divers Cases in Pleas of the Crown, adjudged and determined in the reign of King Charles II. with directions for justices of the peace and others, collected by Sir John Keyling, knight, Lord Chief Justice of the Court of King's Bench, from the original manuscript under his hand; to which is added, the Report of three modern cases, viz. Armstrong and Lisle, the King and Plumer, the Queen and Mawgridge." A pretended second edition appeared in 1739, but the title only was new.

HOLT (Saxon), a wood, by which the names of towns beginning or ending with *holt*, as Buck-*holt*, denote that formerly there was plenty of wood in those places.

HOLT, lately a village, now a town, in Wiltshire, in the hundred of Bradford. It has grown up rapidly from opening a mineral spring of slightly sulphureous water, which, with the establishment of suitable accommodations, has attracted many scrofulous patients. It is a chapelry within the parish of Bradford. The inhabitants amounted in 1811 to 1812, in 1821 to 2415, and in 1831 to 2519.

HOLT, a pleasant market-town in the county of Norfolk, giving its name to the hundred in which it is situated. It is 121 miles from London, has a good market on Saturday, and an endowed grammar-school for thirty boys under the patronage of the fishmongers' company of London, who present from it to a fellowship and scholarship at Sydney College, Cambridge. The inhabitants amounted in 1801 to 1004, in 1811 to 1037, in 1821 to 1348, and in 1831 to 1622.

HOLY GHOST, one of the persons of the Holy Trinity. See TRINITY.

HOLYHEAD, a sea-port town in the island of Anglesey, in North Wales. It is situated on a peninsula at the western side of the island, and of late some great improvements have been made on the harbour, on one side of which is a light-house, on Salt Island, and another to the north-east, giving additional guidance to vessels in the night time. There is a good market on Saturday, and an ample supply of fish when the weather is favourable for taking them. The trade of the place depends chiefly on this being the greatest point of intercourse between England and Ireland, and it has been greatly advanced by the magnificent roads through North Wales, and the finishing of the suspension bridge over the Menai passage. The mails from the capital and from the northern counties arrive every morning at an early hour, and the letters and passengers are embarked immediately in steam-boats, which reach Dublin, in favourable weather, in eight hours. The inhabitants amounted in 1801 to 2132, in 1811 to 3005, in 1821 to 4071, and in 1831 to 4282.

HOLY ISLAND, a small island situated on the coast of England, ten miles south-east of Berwick, in Northumberland. Bede calls it a semi-island, being, as he observes, twice island and twice continent in one day; for at the flowing of the tide it is encompassed by water, and at the ebb there is a passage almost dry both for horses and carriages to and from the mainland, from which, if measured on a straight line, it is distant about two miles eastward, though, on account of some quicksands, passengers are obliged to make so many detours, that the length of the way is nearly doubled. The water over these flats is at spring-tides only seven feet deep. This island was called by the Britons *Inis Medicante*, and also *Landisfarne*, from the small rivulet of Lindi or Landia, which here runs into the sea, and the Celtic word *fahren*, or recess; but, on account of its being the habitation of some of the first monks in this country, it afterwards obtained its present name of *Holy Island*. It measures from east to west about two miles and a quarter, but its breadth from north to south is scarcely a mile and a half. Holy Island, though really part of Northumberland, belongs to Durham; and all civil disputes must be determined by the justices of that county.

HOLY-Rood Day, a festival observed by the Roman Catholics in memory of the exaltation of our Saviour's cross. See CROSS and EXALTATION.

HOLYWELL, a considerable town in the hundred of Mold, of the county of Flint, in North Wales, 207 miles from London. It derives its name from a spring to which numerous pilgrimages were formerly made, and which is still visited by some devout Catholics, who pay their devotions at the place once filled by the image of the patroness, St Winifred. The spring yields a regular and prodigious supply of water; according to one experiment, a hundred tons in a minute. Doubts are entertained of the accuracy of this experiment; but it certainly turns a mill close to the well. In the vicinity of this town are valuable mines of lead, calamine, and copper; and within it are appropriate establishments for rendering these minerals available to the purposes of subsequent manufactures. There are also cotton spinning-mills established upon the stream which issues from the well, between its source and its falling into the Dee. The cotton twist spun at Holywell has a great reputation from its singular evenness. The town is finely situated, the air pure, and the market on Friday well supplied. There is a modern-built parish-church, and four places of worship for Catholic and Protestant dissenters. The population amounted in 1801 to 5567, in 1811 to 6394, in 1821 to 8309, and in 1831 to 8969. Long. 3. 13. W. Lat. 53. 16. N.

HOLZMINDEN, a city of the duchy of Brunswick, in Germany, the capital of the circle of the same name. It stands on the river Weser, and has on its banks excellent quays for landing and shipping goods. It is a well-built town, with a spacious market-place, two churches, a public school moderately endowed, and a good library. It contains 420 houses, and 3600 inhabitants, who are employed in trading on the river, and in various manufactures, especially in iron and steel works, in distilleries, breweries, and tanneries. Long. 9. 9. 55. E. Lat. 51. 50. 6. N.

HOMBERG, WILLIAM, a celebrated chemist, born at Batavia on the 8th of January 1652, was the son of a Saxon gentleman employed in the service of the Dutch East India Company. His father intended him for the army, but having afterwards settled at Amsterdam, William prosecuted his studies at that place, whence he removed to Iena, and afterwards to Leipsig, where he studied the law. In 1674 he was received as advocate at Magdeburg, which had been indebted for a new species of celebrity to the physical experiments of Otto Guericke, and there applied himself to the study of experimental philosophy. Some time afterwards he travelled into Italy, and at Padua applied himself to the study of medicine, anatomy, and botany. He afterwards studied at Bologna; and at Rome he learned optics, painting, sculpture, and music. He then travelled into France, England, and Holland;

took the degree of doctor of physic at Wirtemberg; visited Germany and the North; explored the mines of Saxony, Bohemia, Hungary, and Sweden; and returned to France, where he acquired the esteem of the learned. He was on the point of returning into Germany, when Colbert being informed of his merit, made him advantageous offers, which induced him to fix his residence at Paris. But soon afterwards he lost his protector, and also incurred the odium of returning into the bosom of the Roman Catholic church; and this double misfortune was the more sensibly felt that he had never dreamed of securing for himself any independent means of subsistence. Homberg, already well known for his phosphorus, for a pneumatic machine of his own invention more perfect than that of Guericke, for his microscopes, for his discoveries in chemistry, and for the number and variety of his curious observations, was received into the Academy of Sciences in 1691, and had committed to him the laboratory of that body, of which he was one of the principal ornaments. The Duke of Orleans, afterwards regent of the kingdom, at length made him his chemist, settled upon him a pension, gave him a superb laboratory, and in 1704 made him his first physician. Homberg, having lived for thirty-three years in the Catholic faith, died in 1715. His principal works are, 1. Manière de faire le Phosphore brûlant de Kunckel, 1692; 2. Diverses Expériences du Phosphore; 3. Réflexions sur l'expérience des Larmes de Verre qui se brisent dans le Vide; 4. Expériences sur la Germination des Plantes, 1693; 5. Essais de Chimie, 1702, 1705, 1709; 6. Observations faites par le Miroir ardent, 1702; 7. Analyse du Soufre commun, 1703; 8. Découverte d'une liqueur qui dissout le Verre, 1703; 9. Observations sur les Araignées, 1707; 10. Mémoires touchant les Végétations artificielles, 1710; 11. Manière de copier sur le Verre coloré les Pierres gravées, 1712; 12. Observations sur une séparation de l'Or d'avec l'Argent, par la fonte, 1713; 13. Tracts on different metallic vegetations, on the generation of iron, and on the vitrification of gold. Homberg had occupied himself much with metals, and was not far from believing in the philosopher's stone.

Homberg, a city of Hesse-Cassel, in the province of Lower Hesse, the capital of a bailiwick of the same name. It is walled, and stands on the river Efze, containing 354 houses, and 3050 inhabitants, who have considerable trade in linen weaving, in tanning, and iron, both wrought and cast.

HOMBURG, a market-town of France, in the department of the Moselle, and arrondissement of Sarguemines. It contains 380 houses, and 1620 inhabitants.

HOME, Henry, Lord Kames, an eminent Scottish lawyer, and author of many celebrated works on various subjects, was descended of an ancient family, and born in Berwickshire in the year 1696. In his early youth he was lively, and eager in the acquisition of knowledge. He never attended a public school, but was instructed in the ancient and modern languages, as well as in several branches of mathematics, and the arts necessarily connected with that science, by Mr Wingate, a man of considerable parts and learning, who spent many years as preceptor or private tutor to young Home.

After studying at the university of Edinburgh, the civil law, and the municipal jurisprudence of his own country, Mr Home early perceived that a knowledge of these alone was not sufficient to form an accomplished lawyer. An acquaintance with the forms and practical business of courts, and especially of the supreme court, as a member of which he was to seek for fame and emolument, he considered as essentially necessary to qualify him to become a finished barrister. He accordingly attended for some time the chamber of a writer to the signet, where he had an opportunity of learning the styles of legal deeds, and the modes of conducting different species of business. This wise step, independently of his great genius and unwearied application, procured him, after his admission to the bar, peculiar respect from the court, and proportional employment in his profession of advocate. These qualifications, together with the strength and vivacity of his natural abilities, soon rendered him an ornament of the Scottish bar; and, on the 2d day of February 1752, he was advanced to the bench as one of the judges of the Court of Session, under the assumed title of Lord Kames.

Before this period, however, notwithstanding the unavoidable labours of his profession, Mr Home had favoured the world with several useful and ingenious works. In the year 1728 he published Remarkable Decisions of the Court of Session from 1716 to 1728, in one volume folio. In 1732 appeared Essays upon several subjects in law, viz. *Jus tertii*, *Beneficium cedendarum Actionum*, *Vinco Vincentem*, and *Prescription*, in one volume 8vo. The first produce of his genius excited not only the attention, but the admiration of the judges, and of all the other members of the College of Justice. This work was succeeded, in the year 1741, by Decisions of the Court of Session from its first institution to the year 1740, abridged and digested under proper heads, in the form of a Dictionary, in two volumes folio; a very laborious work, and of the greatest utility to every practical lawyer. In 1747 appeared Essays upon several subjects concerning British antiquities, viz. 1. Introduction of the Feudal Law into Scotland; 2. Constitution of Parliament; 3. Honour, Dignity; and, 4. Succession or Descent, with an appendix upon hereditary and indefeasible right, composed in 1745, and published 1747, one vol. 8vo. Though not in the order of time, we shall continue the list of all our author's writings on law, before we proceed to his productions on other subjects. In 1757, he published the Statute Law of Scotland Abridged, with historical notes, in one volume 8vo; a most useful and laborious work. In the year 1759, he presented to the public a new and very interesting work under the title of Historical Law Tracts, in two volumes 8vo. In 1760, he published, in one volume folio, the Principles of Equity; a work which shows both the fertility of the author's genius and his indefatigable application. In 1766, he gave to the public another volume in folio of Remarkable Decisions of the Court of Session from 1730 to 1752. In 1777, appeared his Elucidations respecting the Common and Statute Law of Scotland, in one volume 8vo. This book contains many curious and interesting remarks upon some intricate and dubious points which occur in the law of Scotland. In 1780, he published a volume in folio of Select Decisions of the Court of Session from 1752 to 1768.

But Lord Kames's mind was much inclined to metaphysical disquisitions. When a young man, he had corresponded with Berkeley bishop of Cloyne, Dr Butler bishop of Durham, Dr Samuel Clarke, and many other ingenious and learned men both in Britain and Ireland. The year 1751 gave birth to the first fruits of his lordship's metaphysical studies, in an octavo volume, published under the title of Essays on the Principles of Morality and Natural Religion. It contained, in more explicit terms than perhaps any other work of a religious theist then known in Scotland, a statement of the doctrine of philosophical necessity, than which it is scarcely possible to conceive any more irrational and unphilosophical, or more essentially adverse to the best interests of morality and religion. Lord Kames continued an advocate of this doctrine until the day of his death; but in a subsequent edition of the Essays, he exhibited a remarkable proof of his candour and liberality of sentiment, by altering some expressions, which, contrary to his intention, had given offence. In 1761, he published an Introduction to the Art of Thinking, in one volume 12mo. This small book was originally intended for the instruction of his own family. His Elements of Criticism appeared in 1762, in three volumes 8vo. This valuable work was intended to show that the art of criticism is founded on the principles of human nature. Before it was published, Rollin's book on the belles-lettres, a dull performance, from which a student could derive little advantage, was generally recommended; but after the Elements of Criticism appeared, the work of Rollin lost its hold of the public.

A further proof of the various pursuits of this active mind was given in the year 1772, when his lordship published a work in one volume 8vo, under the title of The Gentleman Farmer, being an attempt to improve Agriculture by subjecting it to the Test of Rational Principles. In the year 1773, he favoured the world with Sketches of the History of Man, in two vols. 4to. These sketches contain much useful information, and, like all his lordship's performances, are lively and entertaining. They were republished in four vols. 8vo.

We now come to Lord Kames's last work, to which he modestly gives the title of Loose Hints upon Education, chiefly concerning the cultivation of the heart. It was published in the year 1781, in one volume 8vo, when the venerable author was in the eighty-fifth year of his age. Though his lordship chose to call it Loose Hints, the intelligent reader will perceive in this composition an uncommon activity of mind, at an age so far advanced beyond the usual period of human life, and an earnest desire to form the minds of youth to honour, virtue, industry, and a veneration of the Deity.

Besides the books which we have enumerated, Lord Kames published many temporary and fugitive pieces in different periodical works. In the Essays Physical and Literary, published by a society of gentlemen in Edinburgh, we find compositions of his lordship on the Laws of Motion, on the Advantages of Shallow Ploughing, and on Evaporation, all exhibiting evident marks of original thinking.

Lord Kames was as remarkable for public spirit as for mental activity and great exertion. For a long tract of time he had the principal management of all the societies and boards for promoting the trade, fisheries, and manufactures in Scotland; and, as conducive to those ends, he was a strenuous advocate for making and repairing turnpike roads throughout every part of the country. He was in some measure the parent of what was called the Physical and Literary Society, which was afterwards incorporated into the Royal Society of Edinburgh. From what has been said concerning the various productions of his genius, it is obvious that there could be few idle moments in his protracted life. His mind, either teeming with new ideas, or pursuing active and laborious occupations, found incessant employment. In his temper he was naturally warm, though kind and affectionate. In the friendships he formed he was ardent, zealous, and sincere. So far from being inclined to irreligion, as some ignorant bigots insinuated, few men possessed a more devout habit of thought. A constant sense of the presence of the Deity, and a veneration for Providence, dwelt upon his mind. From this source arose that propensity which appears in all his writings, of investigating final causes, and tracing the wisdom of the Supreme Author of nature. Lord Kames died on the 27th of December 1782. As he had no marked disease, but the debility necessarily resulting from extreme old age, a few days before his death he went to the Court of Session, addressed all the judges separately, told them he was speedily to depart, and took a solemn and an affectionate farewell. A full account of his Life and Writings, including much of the Literary History of Scotland, was published by the late Lord Woodhouselee, in two vols. 4to, 1807.

HOME, John, a Scottish dramatic writer of great celebrity, was born at Leith, on the 13th of September 1722. His father, Mr Alexander Home, was town-clerk of that place, and his mother was a daughter of Mr John Hay, a writer, or solicitor, in Edinburgh. He acquired the elementary branches of his classical education under Mr Hugh Millar, master of the grammar-school of Leith, and entered the University of Edinburgh in 1735, where he soon contracted an intimacy with William Robertson, William Wilkie, Alexander Carlyle, Hugh Blair, John Blair, Sir Gilbert Elliot, Sir John Dalrymple, and several others, afterwards well known in the literary world. After having attended the humanity class taught by Mr Kerr, one of the best Latin scholars of the age; mathematics, taught by the celebrated Maclaurin; logic, taught by Dr Stevenson, who contributed more than any other man in Scotland to inspire the young men of that period with a taste for good writing and rational investigation; he proceeded to the study of moral and natural philosophy, under Sir John Pringle and Sir Robert Stewart, and then passed through the usual routine of theological instruction. He was licensed by the presbytery of Edinburgh as a preacher of the gospel, on the 4th of April 1745.

Before he had enjoyed many opportunities of exercising this peaceful function, Scotland became the scene of a civil war; and the ardour of his mind, imbued as it was with a love of enterprise, and a boundless admiration of military glory, prompted him, on the first news of the approach of the rebel army, to join an armed association, formed by the inhabitants of Edinburgh, for the defence of the city. On the 9th of September 1745, he was enrolled in the *College Company of Volunteers*, a corps which was dissolved within a week, when the city was taken possession of by the Pretender's troops. But Mr Home and a few other spirited young men again formed themselves into a more select and efficient company, in the month of November, and subsequently obtained permission from General Hawley to serve in the field. Of this company Dr William M'Ghie was chosen captain, and Mr Home lieutenant. He had the command of the company on the 17th of January 1746, at the battle of Falkirk, where, having received no orders to act, he was an indignant witness of the disgraceful rout of the royal forces, which had fought so well at Dettingen and Fontenoy; and having been one of the last to retreat, he was taken prisoner, with five of his company. They were sent to the Castle of Doun, in Perthshire, on the 25th of January; but Mr Home, with some of his fellow prisoners, escaped on the 31st, by twisting their blankets into ropes, and dropping from the battlements, a height of seventy feet. At this time Mr Home was not less remarkable for the elegance and symmetry of his person, than for his engaging and prepossessing address. His appearance bespoke great vivacity, activity, and energy; his conversation was not merely cheerful, but uncommonly sprightly and animated; and the unceasing kindness which beamed from his countenance, and marked every action of his life, was such as to render him an universal favourite.

In the course of the year 1746, after the death of Mr Robert Blair, minister of Athelstaneford, and author of the well-known poem entitled *The Grave*, Mr Home obtained the presentation to the living, by the interest of Alexander Home of Eccles, afterwards solicitor-general. He was ordained to the charge of the parish in February 1747, and proved very acceptable to the parishioners. During a considerable part of his incumbency, he gave the use of his manse to Mr Hepburn of Keith, a gentleman who had been engaged in both the rebellions in 1715 and 1745, and whose insinuating manners and enticing conversation in some measure reconciled Mr Home to the character of the Jacobites. He boarded himself in the house of a grazier or butcher in the village, at the moderate rate of L.12 a year; but as he passed a great part of his time amongst his numerous friends in the neighbourhood, it is believed that his host was not inadequately remunerated. Mr Home was frequently absent from his lodgings from Monday morning till Saturday night, and though he wrote a considerable number of discourses for the pulpit, he seldom left himself time to finish any one of them. After writing about two thirds of a sermon and committing it to memory, he generally trusted for the remainder to the moment of delivery. These unpremeditated perorations, occasionally eloquent, were delivered with more than his usual vehemence of action, and are said to have been not a little admired by his rustic audience.

Amongst the most intimate friends of Mr Home at this time were Lord Elibank, then residing at Ballancrieff, Dr Robertson, then minister of Gladsmuir, Dr Carlyle of Inveresk, and Mr George Logan of Ormiston, a young clergyman of great promise, who died soon after having been induced, by the solicitation of his ablest contemporaries, to undertake the refutation of David Hume's sceptical writings.

From his earliest years Mr Home had been a passionate admirer of the tragic muse, and about the time of his establishment in the church it was known to his familiar friends that he was engaged in the composition of a tragedy founded on the account of the death of Agis, as given in Plutarch's *Lives.* The play, when completed, was highly approved by his friends Blair, Carlyle, and George Logan.

In 1749, he went with this play to London, having obtained strong recommendations to the attention of several leaders of the republic of letters; but his reception was very discouraging, except amongst his own countrymen. Some objected to the bloodiness of the catastrophe, and to the irregular sequence of the scenes; others to the Scoticisms or vulgarisms of the style. Lord Lyttleton was then reputed the chief arbiter of taste; but no importunity could prevail upon him to read the play, because he did not like to express disapprobation, and if he happened to be pleased, he did not wish to have the trouble of supporting it, as he had lately found almost insuperable difficulty in carrying through one of Thomson's tragedies which he had warmly patronised. One Englishman of some note remarked, that the author had formed himself too much on Thomson's *Seasons* and Lee's *Plays.* "I could not have been more surprised," said Mr Home to a correspondent, "if he had told me that I had formed myself upon Euclid's *Elements* and Maclaurin's *Fluxions.*" He had not a very exalted opinion of the English intellect. "I sometimes hearken to the coffee-house conversations upon poetry and politics, where there are such fellows authors, whose wigs are worth L.3 sterling, that it is ready to make a man of moderate patience *curse his better angel from his side, and fall to reprobation.*" When Garrick refused to bring the play upon the stage, the author, after giving vent to his mortified feelings in an address to the shade of Shakspeare, composed in Westminster Abbey, returned to Scotland, and resumed the labours of his pastoral office, not without devoting a large share of his time to the society of his literary acquaintance, and to the pursuit of his favourite study.

He continued assiduously to cultivate the friendship of Mr Hepburn, from whose sister-in-law, Mrs Janet Denoon, he first heard the old song of *Gil Morrice.* This ballad furnished the hint on which he constructed the tragedy of *Douglas,* in the composition of which he amused himself occasionally the next five years, submitting the successive scenes to the revision of a few friends. His own handwriting was scarcely legible, and the play was repeatedly transcribed by Dr Carlyle. From this circumstance, and from the warm interest which that gentleman took in the success of the piece, he was commonly supposed to have had a principal share in the composition. Sir Gilbert Elliot's criticisms were acknowledged to be particularly valuable, and he also was not unfrequently reputed the author. In February 1755, Mr Home set out for London on horseback, with his tragedy in one pocket, and some clean linen in the other; and was accompanied into Northumberland by a cavalcade of clerical friends, two of whom, Carlyle and Cupples, proceeded with him a stage or two beyond Durham. This play, as well as *Agis,* was rejected by Garrick, not so much, perhaps, owing to any defect in his own taste, as because it did not contain much of that pomp and circumstance which seemed to be the chief attractions of the tragedies which were at this time favourites with the public.

Whilst Mr Home was engaged in the composition of this play, he had not been inattentive to other affairs more nearly connected with the clerical profession. In 1752 he took an active part in the deliberations of the General Assembly, when Mr Gillespie was deposed. The year before, he had made the motion to suspend Mr Adams of Falkirk, for disobeying an order of the General Assembly, and was seconded by Dr Robertson, the first time either had spoken in that house. They were not members next year, but both spoke at the bar with great effect. About this time Mr Home's support was strongly solicited by Dr Cuming, the leader of what was then called the moderate party; but he resolved to act an independent part. He had become a great favourite of Lord Milton, nephew of the famous Andrew Fletcher of Salton; and, as his lordship managed the political affairs of Scotland, under the direction of Archibald duke of Argyll, he took an opportunity of introducing Mr Home to his grace, who was much delighted with his cheerful and fascinating manners, and continued to befriend him ever afterwards. Mr Home paid a visit to the duke at Inverary, in October 1756, and was most kindly received. At this time he was closely connected in friendship with the members of the *Select Society,* established at Edinburgh in 1754.

It was resolved at last, by the friends of the author, in December 1756, to have *Douglas* represented on the Edinburgh stage; and the result far exceeded their most sanguine expectations. Digges performed *Young Norval,* and *Lady Randolph* was personated by Mrs Ward. The theatre was crowded night after night, and the applause of the audience was tumultuous. Not only all the literati attended, but most of the judges and other grave characters, whose presence in the theatre excited great surprise and not a little scandal. Before this time the inhabitants of Edinburgh had not been much accustomed to dramatic entertainments, as the leaders of the church had generally had sufficient influence to induce the civil power to suppress them. In the year 1727, the Presbytery of Edinburgh issued an *Admonition against the Stage;* and, in 1733, in consequence of a sermon on the *Use and Abuse of Diversions,* by Mr George Anderson, a minister of Edinburgh, various pamphlets were published, particularly one by Mr Anderson himself, in which he denounced the stage as an unchristian diversion, and repeated all the arguments against it produced by Prynne, Filmer, Baxter, and Collier. Following the example of their predecessors, this body issued a similar admonition and exhortation to all within their bounds, on the 5th of January 1757, and not only suspended Mr White, minister of Libberton, for having been present at the performance of *Douglas,* but wrote letters to the presbyteries of Haddington, Dalkeith, Ayr, Chirnside, and Dunse, informing against those of their members who had been guilty of the same indecorum. Some of the clergymen accused were allowed to escape with a gentle rebuke; but Dr Carlyle was libelled, as it is called, by his presbytery, at the instigation, as he believed, of an eminent lawyer, then lord advocate, whose conduct on that occasion was afterwards sufficiently avenged by the ridicule heaped upon him in an humorous political satire, by Dr Adam Ferguson, entitled *The History of Sister*

Peg. Several abusive pamphlets against the play and its supporters were known to proceed from the minions of this gentleman, who was then rising to a degree of consequence which soon supplanted the declining influence of Lord Milton.[1]

After the play had been so amazingly successful in Edinburgh, it was eagerly admitted on the stage of Covent-Garden early in 1757; but Garrick still excluded it from Drury-Lane. The triumph of the author was, however, in no small degree abated by the prosecution of his friends in the church courts, and by his own threatened deposition. The subject was brought before the General Assembly by Dr Carlyle in the form of an appeal from a sentence of the Synod of Lothian and Tweeddale; and a decision favourable to the appellant was carried by a great majority of 117 to 37. The result of this vote checked the introduction of a very severe *Overture*, which was intended to have been enacted into a law; and next day another motion was substituted, so lenient as to be seconded by Mr Dempster of Dunnichen, the friend of Home and Carlyle, in consequence of which the assembly passed a declaratory law, prohibiting the clergy from attending the theatre, but not discharging them from writing plays. Immediately afterwards, Mr Home thought it expedient to resign his charge; and having preached a most pathetic sermon, which deeply affected his congregation, he took leave of them in the beginning of June 1757, without having incurred any ecclesiastical censure. He then retired for three months to private lodgings at Braid, near Edinburgh, where he gave the finishing hand to the play of *Agis.*

From the moment when Mr Home resigned his living, the prospects of his worldly prosperity began to brighten. The people of England, ever alive to sentiments of compassion, regarded him as a victim to the rigour of Presbyterian bigotry; and though their critics decried the merits of *Douglas*, as being a faulty and languid composition, not sufficiently relieved by either pathos or elegance of expression, they admitted that it exhibited unquestionable indications of true poetical genius, and a power of awakening the most elevated as well as the most tender emotions. Men of the highest rank and influence expected to gain popularity by patronising the author, who, after being known to possess the good graces of the Dukes of Cumberland and Argyll, was warmly recommended by his friend, Sir Gilbert Elliot, to the Earl of Bute, who then superintended the education of the Prince of Wales, afterwards George III. The Princess Dowager of Wales granted him a pension of L.100 a year, an allowance equal to the value of the living which he had resigned; and assurances were given him of a more ample provision at no distant period.

In one respect, the partiality of his literary friends, and the favour of the great, had an injurious effect on his future fame, not only by producing an impression that he had gained by flattering assiduities what merit alone was seldom known to procure, but by exciting expectations in the minds of numbers that his more mature exertions would far surpass the earliest specimen of his powers as a dramatic writer. The warm encomiums of David Hume were naturally ascribed to the partiality of friendship; but the opinion expressed by Gray the poet, that the tragedy of *Douglas* had "retrieved the true language of the stage, lost for three hundred years," seemed to imply a preference of the muse of Home even to that of Shakspeare himself. The objections of Garrick to the tragedy of *Agis* were no longer urged; and though this was in fact the earliest effort of an unpractised writer, it appeared under the disadvantage of being considered as a work of higher pretensions than that which had already been so well received by the public. It is also to be presumed, that though in its finished state it retained many lofty sentiments of freedom and patriotism, yet, as the author began to breathe the atmosphere of a court, he was tempted to soften some of his boldest images, so that the piece may have lost in spirit more than it gained in polish. It was brought out at Drury-Lane in 1758, and, partly owing to the admirable acting of Garrick in the character of Lysander, had a successful run of nine nights. The author cleared several hundred pounds, but the anticipations of the public were not fulfilled. "I cry," said Gray, "to think it should have been by the author of *Douglas.* Why, it is all modern Greek. The story is an antique statue, painted white and red, frizzed and dressed in a negligee made by a Yorkshire mantua-maker."

In 1759, the *Siege of Aquileia* was first performed at Drury-Lane, but was by no means so successful as Garrick had expected. Garrick and Home were now on the most intimate footing; and as Home listened with much deference to the criticisms of this great actor, and generally followed his advice, the latter, on the other hand, courted the good graces of Home, by consulting him in his difficulties, and soliciting him to act as his friend, or second, in certain quarrels, which threatened to terminate in duels. Early in 1760, Mr Home's first three plays were published in one volume, which was dedicated to the Prince of Wales.

After the accession of the prince to the throne, the Earl of Bute became prime minister; and from this period Mr Home for many years lived constantly with his lordship, at least from October to May, and was well known to possess the first place in his confidence and favour. Mr Home was always most active in promoting the interest of those who called themselves his friends, and conferred the most valuable obligations upon many individuals, who were more forward to solicit his services than to testify their gratitude. But it is well known that he never teased his patron with applications in his own behalf; and it is believed that he might have been overlooked altogether, if Lord Bute had not been prompted by another friend to bestow upon him some honourable and lucrative appointment. A pension of L.300 a year was granted to him in July 1762, and another of equal amount was at the same time conferred on Dr Johnson. In the course of the following year, the place of *Conservator of Scots Privileges at Campvere* was bestowed upon him, the value of which appointment was also L.300 a year; and from this period his name appears annually in the list of members of the General Assembly, as elder for the church of Campvere, under the title of *Lord Conservator*. He regularly attended the meetings of the assembly, and took a lively interest in the proceedings. He had little turn for business, but he occasionally spoke with much energy and effect. He was ambitious to have a seat in the House of Commons, and repeatedly signified his wishes, which at one period might have been easily fulfilled, if he had not been dissuaded by Sir Gilbert Elliot and Sir William Pulteney, not only because they knew that he would be considered as disqualified, by having been in orders, but because they were convinced that, even if that objection were not started, he would make no great figure as a debater. When in London he lived on terms of great cordiality with Armstrong, Smollett, Dr Pitcairn, Dr William Hunter, Mr Wedderburn, afterwards chancellor, and the Honourable Charles Townshend. He had a particular pleasure in fostering rising merit. In the year 1759, he stimulated James Macpherson to collect what were called the *Poems of Ossian;* and he afterwards accompanied him on one of his tours, partly with the hope of sharing in the pleasure of discovering the poetical remains of distant ages, but chiefly with the view of searching for materials which might throw light on the history of the rebellion in 1745.

---

[1] The following are some of the most remarkable pamphlets published on this occasion:—1. Admonition and Exhortation of the Presbytery of Edinburgh. 2. Witherspoon's Serious Enquiry into the Nature and Effects of the Stage. 3. The Immorality of Stage Plays in general, and of the Tragedy called Douglas in particular, briefly illustrated. 4. The Usefulness of the Edinburgh Stage seriously considered. 5. The Tragedy of Douglas analysed. 6. A Letter to Mr David Hume on the Tragedy of Douglas. 7. An Apology for the Writers against the Tragedy of Douglas, with Remarks on that play. 8. The Deposition, or Fatal Miscarriage, a tragedy. 9. Douglas, a Tragedy, weighed in the balances and found wanting. 10. The First Night's Audience, an excellent new ballad. 11. The Stage or the Pulpit, two parts. 12. The Apostle to the Theatre his Garland. 13. The Finishing Stroke, or Nothing, a ballad. 14. The Infernal Council, an excellent new ballad. 15. A Song or a Sermon, a new ballad, Saturday, 29th January 1757. 16. The Admonition, an execrable new ballad. 17. Advice to the Writers in Defence of Douglas. 18. An Epilogue to the Tragedy of Douglas, spoke by the Author. 19. An Argument to prove that the Tragedy of Douglas ought to be Burnt by the Hands of the Hangman [ironical, by Dr Carlyle] 20. The Moderator, Nos. 1 and 2. 21. Votes of the Presbytery of Edinburgh, 29th December 1756. 22. A Letter to the Reverend the Moderator, &c. of the Presbytery of Haddington. 23. A Letter to the Author of the Ecclesiastical Characteristics. 24. The Morality of Stage Plays seriously considered [by Dr Ferguson]. 25. Some serious Remarks on a Pamphlet, entitled the Morality of Stage Plays seriously Considered [by the Reverend Mr Harper, an Episcopalian clergyman]. 26. The Players' Scourge. 27. A Letter to the Author of the Ecclesiastical Characteristics. 28. A Second Letter to the same. 29. Unto the Right Ethereal the Siplers, the Petition of Poor Alexander Bonum Magnum. Most of these are unfavourable to the play (some of them written by Mr Maclaurin, afterwards Lord Dreghorn); others contain very indecorous strictures on the conduct of Drs Cuming, Walker, and Webster, who were active in discouraging the attendance on the theatre, and in prosecuting offending brethren.

In 1769, his tragedy of the *Fatal Discovery*, the fable of which is borrowed from one of the fragments ascribed to Ossian, was performed at Drury-Lane, with indifferent success. At this time the prejudice against Scotchmen was so strong in London that Garrick apprehended a total failure of the play if the author were known. At his suggestion, therefore, the title was altered from *Rivine* to the *Fatal Discovery;* and for some nights the representation was greeted with loud applause, the play being ascribed either to Gray or to Smith. Mr Home's love of praise, however, betrayed the secret, and from that moment the audience sensibly diminished every night. In February 1773, *Alonzo* was brought out, and was well received. This play is recommended by the simplicity of the plot, the harmony of the versification, and the dignity of the sentiments; but some of the incidents are improbable, the language occasionally too mean, the apostrophes too frequent, and it has more eloquent declamation than natural feeling, more graceful description than pathetic effect. The acting of Mrs Barry affected the feelings of the audience so powerfully as to disarm the severity of criticism. To this tragedy, as well as the *Fatal Discovery*, Garrick furnished an epilogue. The theatrical career of Mr Home was closed with the play of *Alfred*, which was represented at Drury-Lane in January 1778. It was listened to the first evening; but a less crowded house was never known than on the second, and after the third performance the author withdrew it.

For many years Mr Home lived chiefly in London. In 1767 he obtained from Sir David Kinloch a long lease of Kilduff, a farm in East Lothian, on which he built a house. In 1770 he married Miss Home (daughter of Mr Home, minister of Fogo, formerly of Polwarth), a lady of very delicate constitution, who, however, survived him several years.

In 1778, when the Duke of Buccleuch raised the regiment of *South Fencibles*, Mr Home's military ardour induced him to accept a commission as lieutenant, the same rank which he had held more than thirty years before; and he gave occasion to some sneers from his graver brethren, by sitting in the General Assembly in his scarlet regimentals. After being nearly two years an officer, he was disabled for military service by a fall from his horse, which, though it did not permanently affect his health, continued through life to impair the vigour of his faculties, and to diminish the flow of his spirits. About this time he left Kilduff, and took up his residence in Edinburgh for the remainder of his life. Till within five years of his death, he was accustomed to pay an annual visit to London; and such was the force of habit, that his friends experienced great difficulty in prevailing with him to desist from these expensive and unnecessary journeys.

In 1798 an edition of his plays was published, in two volumes, now rarely to be procured.

His last work, the *History of the Rebellion in* 1745, was published at London in 1802, in a quarto volume. It had long been understood to be in a state of perfect preparation, but it was not expected to appear in the author's lifetime, as there was reason to apprehend that much of the matter which it contained would prove offensive to some distinguished individuals, whose hostility it was not desirable to encounter. In the first sketches of it, the author is said to have ardently applauded the disinterested motives and gallant conduct of the adherents of the house of Stuart, to whom he had been opposed in the field; and whilst he did ample justice to their devoted attachment and heroic efforts, he was not sparing of the indignation due to the barbarities perpetrated by the prevailing party after the victory of Culloden. Some influence, however, was exerted to hasten the publication, and the author had not the courage to resist the temptation to suppress and qualify many of his first statements. As a composition, it was certainly not improved by what were intended as the finishing emendations; but, if its interest has been weakened, its impartiality has probably been more effectually secured than if it had retained its original form; and, though the book gave much less satisfaction than if it had not been so anxiously expected, its merit has certainly been unduly depreciated. The style, indeed, is negligent, and the reflections not profound; but if the comments of the author are few and obvious, the detail is generally so full as to enable the reader to draw just conclusions; the battles are graphically described, and, as far as the narrative extends, it is entitled to unreserved credit. Perhaps the chief cause why the work was never highly applauded has been, that it is not written so as to gratify the prejudices either of one party or another.

Mr Home died at Merchiston, in the neighbourhood of Edinburgh, on the 5th of September 1808, when he had nearly completed his eighty-sixth year. In private life no man was ever more entirely beloved. His affections were equally warm and stedfast; and much as he had moved in the highest circles, not without pluming himself sufficiently on his intimacy with the great, he never forsook the interest of his friends in humbler stations, or betrayed any expectation of deference from those who were dependent on his good offices. His temper was placid, and though there were occasions on which he manifested some warmth of feeling, he was neither apt to resent injuries nor to inflict pain. He was never known to grudge any exertion which tended to benefit or gratify his friends; and long after the activity of his mind had begun to languish, he continued as eager as ever to confer unsolicited favours, and to use all the influence which he possessed to reward neglected merit. He was alleged to be rather apt to flatter; but the fact was, that he appeared never to discover any defects in the character of those whom he esteemed; and, with all the blindness of a lover to the objects of a first attachment, the overflowing benevolence of his heart disposed him to invest his early friends with every perfection of which human nature is susceptible, and to spread the veil of charity over blemishes and offences. If he had not been early enticed into the vortex of fashion and politics, he might have attained higher eminence as an author; but, in spite of all the temptations of vanity, and the petulant and persevering attacks of envy, he could scarcely, under any circumstances, have proved more amiable as a man. (P. P. P.)

HOME, *Sir Everard*, an eminent surgeon, was born about the year 1755. He was of Scottish extraction, and his connection with the Hunters brought him into notice at an early period of life. At one time he was held in high estimation as a surgical practitioner, and obtained the more substantial advantage of an extensive practice. He had the good fortune to be appointed one of the surgeons to St George's Hospital; and this circumstance, added to the publication of various works which attained a considerable share of celebrity, contributed to extend his reputation, the advantages of which he lived nearly half a century to enjoy. In 1813 he was created a baronet, and was also appointed serjeant-surgeon to the king. For several years before his death, which took place on the 31st of August 1832, in the seventy-seventh year of his age, Sir Everard Home had retired from practice, and sought in private life the repose which his increasing age and infirmities required. Sir Everard was the author of Practical Observations on Stricture, of Lectures on Comparative Anatomy, and of various papers in the Philosophical Transactions; but none of his productions discovers much depth of research, or any great originality of speculation. (A.)

HOMER, the greatest, and perhaps also the least known, of all poets. After so many ages, all the details of his life are still an object of doubt, and even his existence is a problem. Some represent him as a native of Egypt, the son of Damasgoras and Echras, whilst his nurse, a daughter of Horus, priest of Isis, was a prophetess; according to these persons, he played in his cradle with nine turtle doves, and the first accents of his voice resembled the warbling of nine different kinds of birds. Others give him an origin still more illustrious, and seek to ennoble the birth of the poet on whom the far higher distinction of genius had conferred immortality. But whilst his admirers compose for him these splendid genealogies, and even make him descended in the right line from Apollo himself, his detractors see in him only a wretched mendicant, who begged from town to town; a plagiary, who strolled about through the world in quest of the authors who had, before his time, written on the war of Troy; a man of slender parts, easily vanquished in the poetical contest with Hesiod, and other poets. The most celebrated and the least ridiculous of these pretended histories is that which, notwithstanding the doubts and conjectures of several learned men, continues to be attributed to Herodotus; probably because there is something piquant in the notion that the father of history had written the life of the father of poetry. But, however this may be, since Strabo has not disdained to cite as an authority this historical romance, nor the learned Larcher to translate it, we conceive it necessary to exhibit a rapid analysis of its contents.

A certain Menalippus, by birth an Athenian, but settled at Cumæ in Ionia, having married the daughter of a citizen called Homyres, had by her a daughter named Critheis, who after the death of her parents passed under the guardianship of Cleonax, the friend of her father. This Cleonax abused the trust which had been reposed in him, and Critheis became pregnant by her guardian. But the latter, being anxious to conceal the condition of his ward, sent her to Smyrna, where she gave birth to Homer, whom she called *Melesigenes* (from the river Meles, on the banks of which he was born), and where also she was reduced to the necessity of spinning wool for subsistence. After this misfortune, Phemius, who taught literature and music with credit at Smyrna, having frequent occasion to see Critheis, who resided near him, conceived a passion for the lady, married her, and adopted her child. Homer, having become an orphan by the death of Phemius, succeeded to the fortune and the school of his adoptive father, and in the capacity of teacher soon acquired great reputation. But a shipmaster called Mentes, a lover of learning and poetry, having become acquainted with Homer, persuaded the poet to abandon the school at Smyrna, and to accompany him in his voyages. Homer, who already meditated the *Iliad*, and wished to acquire personally the knowledge of different countries, particularly those which he might have occasion to describe, eagerly embraced the opportunity thus offered; and, during several voyages, he failed not to treasure up in his mind whatever he deemed worthy of being remembered. After having visited Italy and Spain, he landed on the island of Ithaca, where he learned many particulars respecting Ulysses; he also visited Egypt, whence he brought into Greece the names of the gods of that country, with the chief ceremonies of their worship; and having finished his travels, he returned to Smyrna, and there completed his *Iliad*. It was his intention to remain in that place; but public favour having abandoned him, he left the ungrateful country, and wandered through several cities in Asia Minor, reciting his verses, and experiencing in turn good and evil fortune. At length he established himself at Chios, where he opened a school, acquired some property, married, became the father of two daughters, and was at last struck with blindness. It was in this retreat that he composed the *Odyssey*; but being desirous to pass into Greece, that he might display his genius upon a larger theatre, he died on his passage, at Ios, one of the Sporades, the inhabitants of which raised on the sea-shore a tomb to his memory.

If in all this narrative there be little that is true, it contains nothing which shocks in the recital; and if, in fact, it be merely a romance, it has at least a certain degree of verisimilitude. Of all the cities which disputed the honour of having given birth to Homer,[1] Smyrna and Chios are those which supported their pretensions by proofs apparently the most plausible. The citizens of Chios boasted of possessing, in the family of the *Homeridæ*,[2] the descendants of this illustrious poet, in honour of whom they had struck a medal, representing Homer, and the river Meles, on the banks of which he is said to have been born. But, amidst so many different opinions, the most probable seems to be that Homer first saw the light near Smyrna; that his life was wandering, like that of the poets of his time; that, in the course of his travels, he visited the Greek cities, composing hymns for the festivals of the gods, and reciting his poems in the religious and public assemblies; that he lost his sight, a deprivation which he felt acutely, and deplored with mournful pathos; and that he lived for some time at

---

[1] Varro reckons seven of them, in a distich which Aulus Gellius (lib. iii. c. 2) has preserved.

Smyrna, Chios, Colophon, Salamis, Rhodos, Argos, Athenæ,
Orbis de patria certat, Homere, tua.

[2] Leo Allatius distinguishes the *Homeridæ* from the *Homeristæ*, a kind of itinerant singers, or minstrels, who recited in public the verses of Homer; but this is a vain dispute of words, and Allatius is here evidently influenced by a desire to ensure to Chios, where he himself was born, the preference over the other cities of Greece which disputed the honour of having given birth to the great poet.

Chios, and died, at an advanced age, in the small island of Ios. But if he was reduced to indigence, and sometimes compelled to beg an asylum during his life, the Smyrneans, Ptolemy Philopator, and others, consecrated temples to him after his death, and the Argives paid him divine honours.

The epoch in which this great poet was born is not less obscure than the history of his life. If we may believe some Greek writers, he was contemporary with the siege of Troy, and had actually witnessed the events which he celebrated in song. But others place his birth at an epoch nearer to ours by eighty, a hundred, and even upwards of three hundred years. Velleius Paterculus, who wrote towards the close of the reign of Tiberius, or about the year 37 of our era, affirms that nine hundred and fifty years had elapsed between the age of Homer and his own time. Pliny and Juvenal, who flourished under Vespasian and Domitian, reckon nearly a thousand years; and Solinus, with some degree of confidence, assigns the epoch of the death of Homer by fixing it in the seventy-second year after the capture and destruction of Troy. According to the Arundelian marbles, he flourished in the tenth century before Christ, whilst other authorities assign the eighth as the period to which he belonged. In this conflict, or rather chaos, of different opinions, the learned Larcher, whose judgment is an authority in matters of chronology, gives a calculation from which it follows that Homer must have been born 884 years before our era; and this epoch appears more reconcileable with the details of the brilliant and sumptuous arts of a refined luxury, which he sometimes retraces, and which appear but little compatible with the rudeness of an age approximating more closely to the time of the Trojan war. The age of Homer indeed is pretty clearly indicated by the following considerations: 1. At the funeral of Patroclus, Achilles celebrates almost all the games which were subsequently in use at Olympia in the most refined period of Greece. 2. The arts of casting in bas-relief, and of engraving on metals, had already been invented, as is proved, amongst other things, by the shield of Achilles; but neither Homer nor Moses makes any mention of painting. 3. The delicious gardens of Alcinous, the magnificence of his palace, and the sumptuousness of his table, prove that the Greeks had already learned to admire luxury and splendour. 4. The Phœnicians had already introduced ivory, purple, and incense from Arabia (as in the description of the grotto of Venus in the Odyssey), *byssus* or fine linen (perhaps cotton), and rich robes. 5. The carriage in which Priam goes to seek Achilles is made of cedar; and the grotto of Calypso is fragrant with that odoriferous wood. 6. The voluptuous baths of Circe indicate a great advancement in luxury. 7. The young slaves of the suitors are described as beautiful, graceful, and fair-haired, such precisely as the fastidiousness of modern times requires as servants. 8. Men dress their hair as carefully as women; a habit with which Hector and Diomede reproach Paris. 9. The Homeric heroes eat nothing but roast meat, the most simple mode of cookery, demanding only a brasier; and this custom continued in sacrifices. Boiled meat came into use afterwards. 10. Lastly, Homer seems to have lived in an age when the strict heroic or feudal right had fallen into disuse in Greece, and popular liberty had begun to appear; for his heroes contract marriages with foreign women, bastards succeed to their fathers' thrones, and many other circumstances unite to show that the heroic or feudal right had expired. From all these authorities, then, we incline to the opinion of those who place the age of Homer long subsequent to that of the Trojan war, though probably not so late as the reign of Numa, with whom he is thought by some to have been contemporary.

But the admitted difficulty, or rather impossibility, of arriving at any thing positive in this respect, induced several writers to fly to the opposite extreme; and whilst some assigned bases to the Homeric chronology which they considered as certain, others called in question the very existence of Homer himself, and supported their opinion with what they deemed incontestable authorities and unanswerable reasonings. The boldest and most singular of these paradoxes is that of Jacob Bryant, who does not, it is true, deny the existence of Homer, but who makes him a native of Thebes in Egypt. In the view of this learned person, Homer was a superstitious poet, who, after having grown old on the banks of the Nile, purloined the poems of the ingenious *Phantasia* deposited amongst the archives of the temple of Isis. According to him, the events of the Iliad and Odyssey were, in the original, mere reminiscences of Egyptian annals; but the adroit plagiary, it seems, transported the scene into the Troad, and disguised under Greek names the gods and heroes of the monarchy of the Pharaohs. Nor was this a solitary extravagance. A learned Dutchman, Crœsius, discovered, in the Odyssey, the history of the Israelites under the patriarchs, and detected the capture of Jericho in the Iliad; whilst another went still further, and gravely maintained that Homer and Hesiod were natives of Belgium. But the hypothesis of Wolf is one of a far higher order; and the weight of such a name must always command a serious consideration of those opinions to which its sanction is deliberately attached.

This distinguished critic and scholar, to whom we are indebted for the best edition of Homer which has yet appeared, attempts, in his *Prolegomena ad Homerum*, to prove that the author of the Iliad and Odyssey is an imaginary being; in Homer he sees a rhapsodist, and nothing more, a minstrel who laid the foundations of that fabric which his successors from age to age slowly raised until it obtained the elevation, symmetry, and unity which we now admire in its general structure. This sceptical hypothesis had not the merit of novelty; but it made little or no impression upon the learned until it borrowed from the talent and erudition of Wolf all the authority necessary to excite general attention, and to call for rigorous examination. Two Frenchmen, of no great distinction, Hedelin and Perrault, are supposed to have led the way in questioning the personal existence of Homer as the author of the Iliad, and to have first suggested some hints of a theory respecting the composition of that poem, which have since been developed with profound learning and wonderful talent by Wolf and Heyne. Hedelin's book, entitled *Conjectures Académiques, ou Dissertations sur l'Iliade*, was published in 1715; and that of Perrault appeared not long afterwards, under the title of *Parallèle des Anciens et des Modernes*. Hedelin had the exquisite judgment to compare the rhapsodies to the *chansons du Pont-Neuf*, and to maintain that the Iliad was made up "ex tragediis et variis canticis de trivio, mendicorum et circulatorum," in the manner of these Parisian ballads. Not long afterwards Bentley expressed a similar opinion respecting the history and compilation of the Iliad. "Homer," says he, "wrote a sequel of songs and rhapsodies to be sung by himself, for small earnings and good cheer, at festivals and other days of merriment: the Iliad he made for the men, and the Odysseis for the other sex. These loose songs were not collected together in the form of an epic poem till about five hundred years after." But a still bolder theory was promulgated in the *Scienza Nuova* of Giambattista Vico, the second and complete edition of which appeared at Naples in 1730; a work which, from its enigmatical style and form, is one of the most obscure books of modern times, but which was intended by its author to form a *Novum Organon* of politico-historical knowledge. Vico's uncompromising reasoning *a priori*,—which, borrowing no assistance from history, will let no history stand in its way,—is not likely to make any one convert to his whole system. But parts of it have of late years been adopted or approved by very distinguished writers;[1] and, in regard to the Homeric poems, he has sketched, with sufficient clearness, the outline of the very theory which is developed with so much ability and force in Wolf's *Prolegomena ad Homerum.* Vico, in fact, distinctly asserts that the Iliad and the Odyssey were first constructed by the Pisistratidæ:—"Ch' i Pisistratidi . . disposero e divisero, o fecero disporre e dividere i poemi d'Omero nell' Iliade e nell' Odissea; onde s' intenda, quanto innanzi dovevan' essere stata confusa congerie di cose, quando è infinita la differenza degli stili dell' uno e dell' altro poema."[2] He expresses a suspicion that the Homer of the Odyssey belonged to the west, and the Homer of the Iliad to the north-east of Greece; and, in his *Discoverta del vero Omero,* he seems to intimate an opinion that Homer himself is an ideal personage, but that his poems are, if we may so express it, the collective voice of the heroic age, in which all history was poetry, and all poetry founded on history. "E certamente," says this modern Heraclitus, "se, come della guerra Trojana, cosi di Omero, non fossero certi gran vestigi rimasti, a tante difficultà *si direbbe ch' Omero fosse stato finto un poeta d' idea, il quale non fù particular huomo in natura.* Ma tali difficultà, est insiememente i poemi di lui pervenutici sembrano farci cotal forza di affermarlo per la mettà, *che quest' Omero sia egli stato un' idea; ovvero carattere eroico di huomini Greci, in quanto essi narravano cantando la loro storia.*"[3]

The substance of this theory, as stated by Wolf and Heyne, is, that whether any such person as Homer ever existed or not, the Iliad and the Odyssey were not composed entirely by him or by any other person, but are compilations, methodised by successive editors, of minstrelsies, the effusions of various poets of the heroic age, and all having one common subject or theme; namely, the war of Troy, and the exploits and adventures of the Grecian chiefs engaged in it. The question as to whether

> The blind old man of Scio's rocky isle

ever lived or not, does not enter as an essential ingredient into the theory so ably elucidated by Wolf and Heyne. That Homer lived and Homer sung, is indeed denied by both, as it had previously been by Giambattista Vico; but, even if the fact of his personal existence were admitted to the fullest extent desired by his unitarian admirers, the material question as to the dispersion of the separate books or rhapsodies, and their reincorporation, or rather their primary construction, into one uniform whole, would still remain to be settled. The theory of which we have traced the origin and development may no doubt appear at first view startling and paradoxical; but, however unlike to any thing of which we may have heard, and however impossible it may be thought in the age in which we now live, there are arguments in its favour, which, with all unprejudiced inquirers, will ever save it from neglect or contempt, and which, in any view, merit the most serious consideration. Of these we shall now proceed to lay a condensed abstract before our readers.

Wolf, Heyne, and their numberless followers in Germany, contend that the argument derived from the apparently undoubting belief of the earliest as well as the greatest writers of Greece, after the Homeric age, and from the general consent of all mankind in the same faith ever since, proves a great deal too much: That, besides the Iliad, Odyssey, Batrachomyomachia, Hymns, and Epigrams, at least twenty other poems[4] were, in former times, ascribed to Homer: That many passages of these poems which are still preserved, contain variations from, and even direct contradictions of, the tenor of the Iliad: That, in the age of Herodotus, the Cyprian verses, and the *Epigoni,* were commonly considered as Homeric poems: That Thucydides quotes the Hymn to Apollo exactly in the same tone in which he quotes or speaks of the Iliad: That nevertheless the general opinion now is that these hymns are not by the author of the Iliad: That Plato expels Homer from his republic, on account, amongst many others, of a well-known passage in the Odyssey:[5] That nevertheless many of the ancients, as well as moderns, who admitted the genuineness of the Iliad, doubted or denied that of the Odyssey: That there is nothing in this weakness of critical discernment, even when imputed to Herodotus, Thucydides, and Plato, which should surprise a Hellenist, seeing that, in the times of republican independence, the investigation of the genuineness of the national compositions formed no part of scientific criticism, much less of the general duties of the philosopher and historian: That as Herodotus and Thucydides quote Homer merely as an historical authority, so Plato censures him for moral or political reasons; and hence a reference to his poems was equally necessary for both purposes, whether the common belief as to their origin were well founded or the contrary: That, in modern Europe, at the period of the revival of letters, this branch of criticism became of paramount importance, and conferred the greatest benefits on awakening learning, by rescuing the genuine relics of ancient Greece and Rome from the mass of fiction and interpolation which had been accumulated on them during seven centuries of barbarism: That, in fact, the early Greeks knew no literature but their own; and, considering how little attention even we, with our different habits and capabilities, ever paid to the mere external history of our earliest works, until a very recent period, we have no reason to think it unaccountable that a chronicler, historian, or philosopher of ancient Greece, should either never have doubted, or but hinted doubts, as to the genuineness of a body of popular poetry, supposed to be of Asiatic growth, and of an antiquity open to nothing but conjecture.

The Wolfian hypothesis rests also upon grounds of external probability. "It is further said," observes Mr Coleridge, "that the art of writing, and the use of manageable materials, were entirely, or all but entirely, unknown in Greece and its islands at the supposed date of the composition of the Iliad and Odyssey;[6] that, if so, these poems could not have been committed to writing during the time of their composition; that, in a question of comparative probabilities, like this, it is a much grosser improbability that even the single Iliad, amounting, after all curtailments and expungings, to upwards of 15,000 hexameter lines, should have been actually conceived and perfected in the brain of one man, with no other help but his own and others' memory, than that it should in fact be the result of the labours of several distinct authors; that if the Odyssey be counted, the probability is doubled; that if we add, upon the authority of Thucydides and Aristotle, the Hymns and Margites, not to say the Batrachomyomachia, that which was improbable becomes morally impossible; that all that has been so often said as to the fact of as many verses or more having been committed to memory, is beside the point in question, which is not whether 15,000 or 30,000 lines may not be learnt by heart from print or manuscript, but *whether one man can originally compose a poem of that length*, which, rightly or not, shall be thought to be a model of symmetry and consistency of parts, *without the aid of writing materials;* that, admitting the superior probability of such an achievement in a primitive age, we actually know nothing similar or analogous; and that it so transcends the common limits of intellectual power, as at least to merit, with as much justice as the opposite opinion, the character of improbability."[1]

---

[1] Niebuhr is largely indebted to the *Scienza Nova* for its views of the early history and real character of the Roman state; whilst the praiseworthy labours of Michelet promise to extend the fame and influence of this singular work farther than the enigmatical obscurity of the original Italian would ever admit of. (See *Principes de la Philosophie de l'Histoire, traduits de la 'Scienza Nuova' de J. B. Vico,* par Jules Michelet, Paris, 1827.)

[2] *Scienza Nuova,* lib. ii. p. 373.

[3] *Scienza Nuova,* lib. iii. c. 7. Mr Coleridge has placed at the end of his account of the origin and preservation of the Homeric poems a translation of Vico's treatise on the discovery of the true Homer.

[4] These were, *Amazonia, Thebaid, Arachnomachia, Geranomachia, Iresione, Epigoni, Epithalamia, Epicichlides, Capra, Ilias Minor,* &c. &c.

[5] Λ'. xi. 487.

[6] "Jam vero non modo nullum tale in Homero extat testimonium rei vel vestigium, nullum ne tenuissimorum quidem initiorum legitimæ scripturæ vel Cadmei muneris indicium, sed, quod longe maximi momenti est, contraria etiam omnia. Nusquam vocabulum *libri,* neque *scribendi,* nusquam *lectionis,* nusquam *litterarum*: nil in tot millibus versuum ad lectionem, omnia ad auditionem com-

This is undoubtedly a strong case; nor is it easy to see how the force of the argument urged by Wolf and his followers can be resisted, unless the facts upon which it mainly depends be disproved. We may be powerfully impressed with the grandeur and *unity* displayed in the Iliad; this impression may be strengthened by more frequent study of the general effect of the poem; and we may feel reluctant to abandon the ancient faith, with which so many interesting recollections and associations are entwined: But, as long as the external facts remain unrefuted, "the internal evidence of the unity of design" will never prevail over the conclusion deduced from them. Mr Milman, indeed, seems to think, that, on the general question of the origin of letters, the mass of authorities collected with great industry, and the arguments urged with equal ingenuity by Kreuser,[2] in some degree endanger Wolf's hypothesis as to the recent introduction of writing into Greece, that is, scarcely prior to the time of Solon. But he admits it to be "undoubtedly embarrassing that, if writing was common in the days of Homer, no allusion, except in one doubtful passage,[3] should be found, in either of the great poems, to an art, which might at first sight appear to be necessarily mingled up with all the transactions of war or pacification, of public and private life." Besides, the precise fact, whether alphabetical characters were absolutely unknown in Greece in the age of Homer, is declared by Heyne to be immaterial to the argument; because, whether known or not, it is certain that down to a period later by two centuries than the latest date assigned as the era of Homer, there were no materials which a Greek author could have employed for the ordinary purposes of composition. It is of no avail to prove that some Greeks had the art of carving on marble or on wood; nor is the difficulty removed by presenting a blind poet with a pen of iron and some plates of lead. If there be any weight in the objection, that no one person could have composed the Iliad and the Odyssey by the force of mere mental retention alone, nothing will ever dispose of it except a demonstration that the poet had some manageable substance upon which to write. The main point, as Mr Coleridge has most justly observed, is not whether poems of such length might not be preserved by memory, *when once composed*, but *whether they could have been constructed in the mind of the bard, without the assistance of letters and writing materials*, to record the fleeting thoughts which passed in quick succession, and were succeeded by others hurrying forward in unceasing and inexhaustible rapidity. The preservation of poems by memory, when once composed, and their oral transmission from age to age, may at once be conceded, because it leaves unimpaired the force of the argument founded upon the moral impossibility of any one person having both composed and retained in his mind, as well as communicated to others, as many as thirty thousand verses.

The more sagacious and candid of those who maintain the unity and authorship of Homer have accordingly felt and acknowledged the force of Wolf's argument. It is indeed admitted by Milman, one of the ablest of his opponents, that even Kreuser's argument in favour of the early introduction of letters and writing into Greece leaves the main question undecided; and, besides, Kreuser himself is a follower of Wolf upon the fundamental point in dispute. In an essay read to the academy of Berlin, the author, M. de Mérian, adopts the same position as Wolf; he denies to Homer the use of writing materials, but says the poet might have done very well without them. This, however, is cutting the knot, not resolving it. The material issue is, Could the poet do at all without them? Of the cases cited by M. Mérian, one is not in point, and the other is unsupported by authority. After many irrelevant instances of learning by heart from book or recitation, he alleges the example of the Italian improvvisatori, and that of Tasso, who, he says, composed four hundred stanzas of his *Gierusalemme Liberata*, equal to 3200 verses, without ever writing them down. The story, however, is not authenticated by any kind of evidence; and unless there be Tasso's own word for it, who will believe that he never tried one of those stanzas in a written form? Besides, it is well known that, during many years of learned leisure, Tasso meditated and arranged the plan of his poem, of which he drew up numerous sketches; so that these four hundred stanzas were, at most, but the filling up of a picture, the outline of which had already been prepared. As for the improvvisatori, it is sufficient to observe that, with a tolerable stock of common-places in their heads, and with a language on their tongues, one half of which rhymes to the other, these people may, with a little practice and a very small exertion of skill, pour forth verses, as they are called, to almost any extent. But what, we would ask, has such a trick as this to do with the mental composition and correction of thirty thousand hexameters of the Iliad and Odyssey? Cesarotti, it is true, talks gravely of Macpherson's *Ossian*, which he translated, as an instance of poetry of considerable extent, composed by a poet to whom writing was unknown. This, however, is producing one hypothesis which,

---

parata; nulla pacta aut fœdera nisi coram; nullus veterum famæ fons præter memoriam et famam et illitterata monumenta; ex eo Musarum, memorum dearum, diligens et in Iliade enixe repetita invocatio; nullus in cippis et sepulcris, quæ interdum memorantur, titulus; non alia ulla inscriptio; non æs signatum aut facta pecunia; nullus usus scripti in rebus domesticis et mercatura; nullæ geographicæ tabulæ; denique nulli tabellarii, nullæ epistolæ, quarum si consuetudo fuisset in patria Ulyssis, vel si πτυκτοι πινακες percontationibus procorum et Telemachi sufficissent, procul dubio Odysseam aliquot libris breviorem, aut, ut Roussavius conjiciebat, omnino nullam haberemus." (Wolfii *Prolegom. ad Homerum*, pp. 88, 89, 90.)

[1] Coleridge, *General Introduction to Homer*, pp. 38, 39. London, 1834, second edition.

[2] In his *Vorfrage über Homeros*.

[3] "The *silence* of Homer," says Mr Milman, "after all the only extant authority for the Homeric age, is the great difficulty, if indeed he is silent, and if the fatal characters, the σηματα λυγρα of the letter of Bellerophon, were but symbolic or hieroglyphic signs." (*Quarterly Review*, vol. xliv. p. 141.)

to say the least of it, is doubtful, to prove another the truth of which is denied. In fact, all unprejudiced critics are pretty well agreed as to the history and character of the English Ossian; and it is now generally understood and believed, that Macpherson treated the legendary poems ascribed to the Celtic bard, much in the same fashion as the Pisistratidæ are supposed to have done in the case of those attributed to Homer, fusing a number of detached fragments into one mass, filling up interstices and vacuities with a sort of cement prepared by himself, and thus imparting to the whole (as in *Temora*) an *unity*, which certainly could not have been predicated of the materials with which he worked. The Ossian of Macpherson is, in truth, an instance in point against the principle stated by Cesarotti, or rather in favour of its opposite. In the affecting narrative of the imprisonment of Silvio Pellico,[1] we are indeed informed that he and his friend Maroncelli, during their confinement, composed many thousand verses, without the use of writing materials, and with nothing but the power of memory upon which to rely for the preservation of their compositions. This is no doubt one of the best authenticated instances of the power of memory in composition which is anywhere to be found. But still, before even this can be admitted as a pertinent example, it will be necessary to see the verses so composed, and to determine the relation which they bear to the poetry of the Iliad and the Odyssey; for it is evident that the point in dispute cannot be affected by the mere fact of any number of loose lines having been composed under circumstances so extraordinary, by men entirely separated from the living and active world. Improvisation by itself is nothing. The question is, could a couple of epics, possessing all the qualities requisite in the very highest species of poetry, have been composed and preserved without the aid of writing materials? This is the real issue. Milton was struck with blindness as well as Homer; but the verses which *he* dictated, after he had been deprived of his sight, were immediately committed to writing by faithful and devoted amanuenses. Would they ever have been heard of, if Milton had been as destitute and helpless as Homer is represented to have been?

Further, it is urged that the artificial construction of the plots of the Iliad and Odyssey, so commonly relied on as an argument for the unity of these poems, is in fact a complete demonstration that their present form cannot be genuine. That the cyclic poets who were contemporary with Homer, or followed in the order of time his age, all composed their works on a plan the very reverse of that which the critics praise so highly in the Iliad and Odyssey, is established by the censure of Horace, and the testimony of all antiquity. This may be seen, as well from the poem of Quintus Smyrnæus, which is founded on the *Æthiopis*, *Ilias Parva*, and the *Ilii Excidium* of Arctinus and Lesches, as from the epitomes of many other old cyclic poems still preserved in the fragments of the *Chrestomathia* of Proclus, if such evidence be not superfluous. The authors of the Dionysiacs, Thebaids, Epigoniads, Naupactica, Genealogies, and other works of that sort, never dreamed of rushing *in medias res*, as it is said that Homer does; never laid distant trains for future catastrophes; never carried on parallel lines of narrative; never concerned themselves about the critical canon of a beginning, a middle, and an end. They uniformly commence *ab ovo*, and conclude when the war or the pedigree is at an end. They have no hero in favour of whose dramatic superiority all others are depressed; they have no single primary action, relieved by episodes; they are ignorant of concealments, recognitions, windings-up, and all other cognate artifices. One story follows another, in the order of mere history, just as in the Indian and Persian epics, in the northern Eddas, in the Spanish poem of the Cid, and in the early chronicles of every nation with which we are acquainted; the skill and fire of the poet are shown, not in the artifice of grouping a multitude of figures into one picture, but in raising admiration by the separate beauty of each successive image or delineation. They tell the tale as the tale had been told to them, leaving out nothing. Now, if the Iliad and the Odyssey, such as we actually have them, were previously in existence, or if any poems so constructed were publicly known, soon after the latest date assigned to Homer, how are we to account for the undeniable fact that this splendid example did not find a single imitator amongst the contemporaries or the followers of Homer for centuries afterwards? It can scarcely be said that no poet arose of sufficient genius to effect this. The names of many of the old heroic poets were celebrated in the best ages; and to rival the plots must certainly have been found an easier task than to equal, far less excel, the poetry of the Homeric epics. Some attempt of this sort might at least have been expected; and what the lowest poetaster now does first, and sometimes does best, could not certainly exceed the powers of Hesiod and the authors of the *Theogonia*. Yet we meet with nothing of the kind. "Quintus Smyrnæus, or Calaber," says Mr Coleridge, "composed his books as a supplement to the unfinished Iliad. We may not rate Quintus very highly as a poet; but have we any right to set him down for such a heavy fool as to have ventured upon the completion of a divine poem, which Aristotle had declared absolutely perfect in its plot, if the numerous examples of former writers of supplements had not been lying before his eyes? Suppose, for a moment, that the Iliad handed down to us had ended, as surely it might have ended, in the death of Hector, and the return of Achilles in triumph to the Grecian camp; and that the substance of the last two books had been added by Quintus in the beginning of his supplement; should we have commended him the more for sagaciously detecting the want of finish, and the premature termination of the narrative? And is it not possible that Aristotle might have lauded the plot of the Iliad nothing the less, if the catalogue of the ships and troops had never been inserted?"

Upon the whole, then, Homer, according to this hypothesis, was the ideal or heroic character of the Greek people, relating its own history. This is the general deduction from all the reasonings of Wolf and his followers, who contend that every thing which is absurd and improbable in Homer, as hitherto conceived, becomes appropriate and even necessary in the Homer thus supposed. 1. In reference to the uncertainty respecting the country of Homer, they observe, that if the people of Greece contended amongst themselves for the honour of having given birth to him, and if all claimed him as a citizen, it was because they were themselves Homer. 2. The poverty and blindness of Homer were those of the rhapsodists, who, being blind (whence their Ionian name of ὁμηροι), had the more powerful memories. 3. Homer composed the Iliad in his youth, that is to say, in the infancy of Greece, when she was all burning with sublime passions, with pride, resentment, and revenge. Greece, therefore, in her infancy, would admire

---

[1] Maroncelli nel suo sotteraneo avea composti molti versi d'una gran bellezza. Me li andava recitando, e ne componeva altri. Io pure ne componeva, e li recitava. E la nostra memoria esercitavasi a ritenere tutto ciò. Mirabile fù la capacità, che acquistammo di poetare lunghe produzioni a memoria, limarle e tornarle a limare infinite volte, e ridurle a quel segno medesimo di possibile finitezza che avremo attenuto scrivendole. Maroncelli compose cosi a poco a poco, e ritenne in mente parecchie migliaja di versi lirici ed epici. Io feci la tragedia de Leoniero da Dertona e varie altre cose." (*Le mie Prigioni*, c. 75.)

Achilles, the type or hero of force. 4. But Homer composed the Odyssey in his old age, when the passions of the Greeks began to be cooled by reflection, the mother of prudence. Greece would, therefore, naturally admire Ulysses, the type or hero of wisdom. In the youth of Homer, the pride of Agamemnon, the insolence and violence of Achilles, pleased the Greeks; in his old age they had begun to take pleasure in the delights of Calypso, the voluptuousness of Circe, the songs of the Sirens, and the sports of the suitors of Penelope. 5. The individual character of Homer having thus disappeared, the poet, or rather the poetry, becomes at once justified from all critical censures respecting the lowness of the thoughts, the grossness of the manners, the barbarism of the comparisons, the idioms, the licenses of versification, the discrepancy of dialects, and finally, for having elevated men to the rank of gods, and degraded gods below the level of men. 6. To Homer is assigned the privilege of having alone possessed the faculty of inventing the poetical fictions of Aristotle and the heroic characters of Horace; the privilege of an incomparable eloquence in his savage similes, his terrible pictures of the dying and the dead, and his sublime delineation of the passions, with the merit of a style at once simple, grand, and picturesque. All these qualities belonged to the heroic age of Greece. 7. Homer is henceforth assured of three immortalities; of having been the founder of civilisation in Greece, the father of all the other poets, and the source of the different systems of philosophy afterwards promulgated in his country; titles which could not possibly belong to Homer such as the world has hitherto imagined him. The Homer of the schools could not be regarded as the founder of Greek civilisation, because, from the epoch of Deucalion and Pyrrha, that civilisation had been commenced by the institution of marriage. He could not be regarded as the father of poets, because Orpheus, Amphion, Linus, and Musæus, to whom some chronologers add Hesiod, had flourished before his time. According to Cicero, there were many heroic poets prior to Homer; and Eusebius names Philammon, Thamyris, Demodocus, Epimenides, Aristeas, and others. Nor, finally, could he be the source of the Greek philosophy; for the philosophers did not derive their doctrine from, but engrafted them upon, the Homeric fables. Homer only afforded to the philosophers an occasion of meditating on the highest truths of metaphysics and morals, giving them, in addition, great facility in illustrating their speculations.[1]

The more we read the more we admire the two immortal poems of Homer, and the less are the generality of persons inclined to doubt that they were conceived by one and the same mind; whilst the infinite art by which the innumerable parts are connected and arranged forms perhaps the most remarkable feature in the Iliad and Odyssey, as well as the best argument for the unity of their authorship, and the individuality of Homer. In these poems, according to Mr Milman, "there is nothing of the elaborate art of a later age; it is not a skilful compiler arranging his materials so as to produce the most striking effect; the design and the filling up appear to be evidently of the same hand; there is the most perfect harmony in the plan, the expression, the versification; and we cannot, by any effort, bring ourselves to suppose that the separate passages, which form the main interest of the poem, the splendid bursts, or more pathetic episodes, were originally composed without any view to their general effect; in short, that a whole race of Homers struck, as it were by accident, all these glorious, living fragments, which lay in a kind of unformed chaos, till a later and almost mightier Homer commanded them to take form, and combine themselves into a connected and harmonious whole."[2] Another circumstance to which the advocates of the unity and authorship of Homer attach very great importance, is the perfect consistency of the characters in the different parts of the poem. It is quite inconceivable, they think, that there should have been a sort of conventional character assigned to different heroes by the minstrels of Greece. "To take Mr Coleridge's illustration of the ballads on Robin Hood," says Mr Milman; "in all these, bold Robin is still the same frank, careless, daring, generous, half-comic adventurer: So Achilles may have been by prescription,

Impiger, iracundus, inexorabilis, acer;

Ajax heavy and obstinate, Ulysses light and subtle; but can we thus account for the finer and more delicate touches of character, the sort of natural consistencies, which perpetually identify the hero, or even the female, of one book, with the same person in another?"

Some of those persons who have written upon the same side of the question as Mr Milman, and indeed Mr Milman himself, are inclined to doubt whether the poems of Homer, consistent and harmonious as they now appear, could have been preserved by tradition alone; and an able French critic has condemned the opinion "qui, en admettant qu'Homère soit l'auteur de l'Iliade et de l'Odyssée, veut qu'il en avait jamais écrit un seul vers, et que restés, en dépôt, dans sa memoire, il les allait réciter de ville en ville, afin d'obtenir de la pitié et de l'admiration publique, les secours que sollicitait sa profonde indigence. Supposer," adds the same writer, "que la tradition orale a seule conservé deux poèmes aussi étendus, pendant le long espace de temps ecoulé entre Homère et les premières editions connues; attribuer aux rhapsodes une portion considerable de ses ouvrages, c'est franchir toutes les bornes d'une critique raisonable. Comment se flatter, d'ailleurs, d'avoir fait une découverte echappée aux critiques de l'antiquité les plus célèbres, et qui ont apporté un soin si religieux à la révision des poèmes d'Homère, depuis Aristote jusqu'à cet Aristarque, dont le nom est devenu synonyme de critique par excellence?" All this, however, seems to be more plausible than sound. For, in the first place, if the art of writing was unknown in Greece in the age of Homer, or at least confined to carving on wood, or engraving on stone or metal, it follows that, for a certain period, the poems of Homer must have been preserved by oral tradition, because there practically existed no other method by which they could be handed down from one age to another. If it be impossible that two poems so extensive could have been preserved by oral tradition, then it is at least equally so that they could have been composed at the period to which they are commonly referred. Secondly, it is no argument whatever against a discovery in criticism to tell us that, if it were well founded, it could not have escaped the most celebrated critics of antiquity, from Aristotle to Aristarchus, who had applied themselves, with religious care, to the revision of Homer. This kind of argument, if sound, would cut down almost every discovery. Bacon discovered and explained the method of reasoning by induction, which had escaped

---

[1] To the praise here bestowed on Homer, may be subjoined that of having been the most ancient historian of paganism who has come down to our times. "His poems," says Mr Coleridge, "are two great treasure-houses, in which the manners of the first ages of Greece are preserved. But the lot of the Homeric poems has been similar to that of the laws of the Twelve Tables. On the one hand, the world has ascribed those laws to the Athenian legislator, from whom, it is said, they passed to Rome, whilst no one has seen in them the history of the common law of the heroic tribes of Latium; on the other, the world has believed the poems of Homer to have been the work of the rare genius of an individual, instead of discovering in them the history of the common law of the heroic people of Greece." (*General Introduction*, p. 98.)

[2] *Quarterly Review*, xliv. p. 154.

Aristotle and all his successors; Newton discovered the law of gravitation, which, in its application to explain the motions of the heavenly bodies, and connect the whole solar system, had never been so much as suspected even by the most illustrious of his predecessors; Young, with rare sagacity, found out the method of interpreting the Egyptian writings, monumental and civil, which so many persons had, through a long tract of ages, sought for in vain. But were it now to be said, in objection to these discoveries, as M. Durivier has said in opposition to the hypothesis of Wolf and his followers, how could their authors flatter themselves with having found out what so many illustrious men had failed to discover? the answer would be, that each of these discoveries must be judged of by the direct evidence produced in support of it; that the increase of knowledge is progressive; and that, with regard to the particular case in question, the science of criticism is, in a great measure, one of modern growth.

To this succinct analysis of the different opinions entertained respecting Homer, succeeds naturally the critical history of his works. He had composed, or at least the ancients attributed to him, a large number, of which a catalogue may be found in the *Bibliotheca Græca* of Fabricius, and in the *Chrestomathia* of Proclus. Of the greater part there remain only the titles, about which even the learned are not always agreed. We should doubtless have little to regret in the loss of the Batrachomyomachia, a burlesque production, in which, with the exception of some details and verses, we find no traces of the genius and style of Homer; or in that of the Hymns, which are twenty-four in number, amongst which two or three have been supposed to belong to Homer. On this subject the reader may consult two critical letters of Rhunken, in his second edition of the Hymn to Ceres, Leyden, 1782; Mitscherlich, Ilgen, Matthiæ, and Hermann, have also published editions of these Hymns, which are valuable for the critical accuracy of the text, and the conjectures as to their supposed dates and authors. The epigrams and smaller poems bear no stamp of authenticity, and hence we may dispense with entering into any particular statement concerning them. It is in the Iliad and the Odyssey alone where we must seek for, and where we will find, the genius of Homer in all its force, and in all its splendour and originality.

If we can credit the statements of Ælian and Plutarch, it was Lycurgus, the celebrated Lacedæmonian lawgiver, who first collected, in Ionia, the scattered fragments of the poems of Homer, united them together, and introduced them into the Peloponnesus. But the glory of arranging them in the order in which they have reached us was, it seems, reserved for Pisistratus, who brought them to Athens, and for his son Hipparchus, who ordained that they should be recited annually during the Panathenaic festival. This fact, related in the *Hipparchus*, a dialogue attributed to Plato, is confirmed by the authority of Cicero, who concedes to Pisistratus, seconded by the poet-philosopher Solon, the merit of having put into order the verses of Homer, which he found in a state of confusion. After the edition of Hipparchus may be mentioned that which Aristotle revised by the advice of Alexander, and which the conqueror, an enlightened friend of letters, deposited in the precious casket which he had found amongst the treasures of Darius. But notwithstanding the authority of Plutarch, who sometimes placed too much reliance on memoirs evidently unworthy of confidence, this famous edition of the casket had, according to Strabo, been revised by Calisthenes and Anaxarchus, and was only presented to Alexander by his illustrious instructor. It is possible, however, that a second revision, enriched with the remarks of Aristotle himself, may have been made under the eyes of the Macedonian conqueror. Before Aristotle, Cynethus of Chios, Stesimbrotus, Theagenes, and Antimachus of Colophon, had already undertaken to comment on the text of Homer. The scholia of Venice, published by the learned Villoison, leave no doubt whatever as to this fact. We have not the same certainty respecting the editions of Cassander king of Macedonia, and Ptolemy Evergetes II. king of Egypt, whatever may have been said by Athenæus, Casaubon his learned interpreter, and the second Burmann. But it was the school of Alexandria which began to give truly classical editions of the works of Homer; Zenodotus of Ephesus, Aristophanes of Byzantium, Aristarchus, and Crates, occupied themselves not only with the revision, but also with the critical explanation, of the text; and Aristarchus is said to have first divided the Iliad and the Odyssey each into twenty-four books, a division which appears so natural and judicious that it has been constantly adopted ever since. So much for the Greek editors of Homer; let us now pass on to his interpreters.

At their head stands Didymus, a grammarian of Alexandria, who flourished under the reign of Augustus. He had enriched several poems with his commentaries; but the scholia on the Iliad and Odyssey printed with his name are evidently not his, and are neither of the same epoch nor by the same hand; in fact, he is often cited in them himself, and mention is made of writers who flourished at a subsequent period. With regard to their literary merit, the remarks, purely grammatical, are only simple glosses on the text; but those which relate to the subject-matter are not without ability, and may be consulted with advantage. This compilation, extracted partly from Didymus, and partly from various other commentators whose names are not mentioned, contains what are usually called the *lesser scholia*. Those on the Iliad were published, for the first time, at Rome, in 1517, folio, and those on both poems united, at Venice, in 1528, in two vols. 8vo. Soon afterwards, that is, from 1542 to 1550, appeared the great work of Eustathius on Homer, which was printed at Rome, in four vols. folio, and included the beautiful table of Devaris. This work, which is merely a compilation from the scholiasts and commentators who had preceded the learned archbishop of Thessalonica, presents nevertheless an immense repertory of literary and grammatical erudition. But it could have been wished that a more severe criticism had directed this vast compilation, or that an able and practised hand had made from it a judicious extract, which might have put into circulation riches almost unknown, or only accessible to the small number of persons who are profoundly skilled in the Greek language. The same observation may be applied to the valuable scholia discovered and published at Venice by Villoison.

We shall not attempt here to give a detail of the numerous editions of Homer. His works complete, including the Iliad, the Odyssey, the Batrachomyomachia, and the Hymns, were printed for the first time at Florence, in 1488, in two vols. folio, under the superintendence of Demetrius Chalcondylas, assisted by another Demetrius from the island of Crete. The printer, Bernardo Nerli, dedicated the collection to Pietro, son of Lorenzo de' Medicis. This rare and precious edition was faithfully reproduced, with a few corrections, in 1504, by the Aldine presses, at Venice, in two vols. 8vo. But the second Aldine edition of 1517 presents sensible differences in the text, which the subsequent editions reproduce, till that of 1528 inclusively. This is what may be called the first age of the editions of Homer. The second dates from Henri Etienne, who, with the assistance of an ancient manuscript, and the commentaries of Eustathius, collected a certain number of various readings, which he gave upon the margin, or developed, along with his own conjectures, in the notes of his beautiful work entitled *Poetæ Græci principes Heroici*

Carminis, Paris, 1566. With Barnes the Hellenist, who was celebrated in his own time, but whose reputation must necessarily diminish with the progress of philological criticism, commences a third epoch, which may be denominated that of Clarke, or perhaps of Ernesti, who improved upon the labours of Clarke, as Clarke had improved upon those of his predecessor Barnes. But he did not dissemble that his edition still left much to be desired; and he modestly admitted that he had only prepared materials for future editors. Such an editor as Ernesti appears to have contemplated was found in the person of Wolf, who, in 1784 and 1785, published at Halle, in Saxony, a complete edition of Homer, the superiority of which, in regard to correctness, was soon generally acknowledged. This edition was distinguished for an exact and severe revision of the text; and in it the learned professor had already announced the system afterwards developed and adopted by him, when Villoison published his famous edition of the Iliad, in folio, Venice, 1788. This edition occupies too important a place in modern philology, and, as some think, concerns too deeply the glory of Homer individually, to be passed by with a simple notice, or without entering into some details. Villoison was busily occupied at Venice with the publication of his *Anecdota Græca*, when, by accident, he discovered, in the library of St Mark, a manuscript of Homer, which, in his judgment, belonged to the tenth century, and was consequently anterior by two hundred years to the Commentaries of Eustathius. This manuscript contained the Iliad entire, accompanied with an immensity of scholia, abridged from those of Zenodotus, Aristophanes, Aristarchus, Crates Mallotes, Ptolemy of Ascalon, and several other celebrated grammarians. But that which particularly struck him, was observing the margins filled with asterisks, daggers, and all the different signs adopted to distinguish verses supposed to have been altered or transposed, from those the authenticity of which was universally recognised. The publication of the work did not fail to realise the great hopes which the learned of Europe had conceived from its mere announcement, and the success of the edition was complete. But it confirmed Wolf more than ever in the opinion that it was to the critics of Alexandria that recourse must be had in order to recover and reconstitute the true text of Homer; and, fortified by the new proofs of the truth of his assertion which he conceived to have under his eyes, he ably profited by the assistance which these ancient scholia afforded him, and made no difficulty in substituting for the ordinary readings of the text the variations which appeared to him to be demonstrated. Thus, by a singular chance, the beautiful monument elevated to the glory of Homer by one of the most famous Hellenists of his age, became the basis of a system calculated to deprive Homer of the admiration which, for ages, had been lavished on him. Villoison was so much affected by this circumstance that he repented of having ever published his Iliad. That of Wolf, accompanied with the Odyssey and the Hymns, re-appeared at Leipsig in 1804, in four vols. small 8vo. This edition adds to its other merits that of a typographical execution which does much honour to the press of M. Goschen. The edition of the Iliad by Heyne, in eight vols. 8vo, which appeared at Leipsig in 1802, has not completely justified the expectations which might have been entertained of such an editor. His principal merit consists in presenting a clear and exact interpretation of the text, and in collecting, in the *Excursus* and Commentaries which accompany it, all that is important to be known for the perfect understanding of Homer. The doctrine of Heyne on the *spirits* rough and smooth (*asper et lenis*), which, according to him, were much more strongly aspirated in the time of Homer, and pronounced like the Æolic digamma, has met with more adversaries than partisans; although it explains very well how certain syllables, naturally short, become long at the end of a word, when the following one begins with a vowel, and causes to disappear the hiatuses which are of so frequent occurrence in the verses of this great poet.

From the commencement or towards the middle of the sixteenth century, Homer was translated into prose and verse amongst the Italians, the English, the French, the Spaniards, and other nations; but we shall only notice those versions which occupy a place more or less distinguished in literature. In Italy the most esteemed are those of Salvini, Cerutti, Cesarotti, and Monti; Salvini, however, translated all that remains of Homer, but the others confined themselves to the Iliad. In England, the translation of Pope threw into the shade those of Chapman, Ogilvy, and Hobbes; but many, nevertheless, prefer to it that of Cowper, as more exact, and preserving better the simple and natural colour of the original; whilst some are of opinion that the recent version of Sotheby, the accomplished translator of Wieland's *Oberon* and Virgil's *Georgics*, is, in several respects, superior to all its predecessors. The French have, in prose, Madame Dacier, Bitaubé, Lebrun, and Dugal-Montbel, each of whom is distinguished for some particular merit. Of the French translations in verse we shall only notice two; those of Rochefort and of M. Aignan, which are both considered excellent. The Germans attach much importance to the versions of Bodmer, of the Count de Stolberg, brother of the translator of Sophocles, and of Voss, all of whom have translated Homer into hexameter verses; a system of versification which prevailed in that school, and which was applied to the ancients, with what success we shall not venture to pronounce. Spanish literature contains no good translation of Homer. The most recent, and, comparatively speaking, the best, is that of Don Saverio Malo, a gentleman employed in the Royal Library at Madrid.

We shall not expatiate here on the literary merit of the prince of poets. It is too generally known, and too deeply felt, to require any exposition at our hands. Besides, what addition could we hope to make to the admirable Essay of Pope on the Life and Writings of Homer; to the *Discours Préliminaire* of Rochefort; and, above all, to the eloquent eulogium which the Abbé Barthélemy puts in the mouth of the Scythian Anacharsis? The dissertations of Lamotte are also, in their kind, so much more honourable to the author or authors of the Iliad and Odyssey, that the number and severity of the criticisms contained in them give to the praise a character more solid and less equivocal. The authority of genius is powerful, nay universal. That of Homer has, for thirty centuries, presided over the destinies of almost every literature of the world. It was from the works of the first and greatest of poets that Æschylus, Sophocles, Euripides, and others, derived not only the subjects of their tragedies, but the spirit and sentiments by which these are animated, and the varied charms of that style of which Homer possessed the secret, and left them a model. It was to his genius that the epic poets, as Virgil and Tasso, were indebted for their sublime beauties; it was from his works that the greatest artists of ancient and modern times borrowed their finest conceptions; and both are the more elevated in proportion as they approach nearer to their great model. In a word, as Homer has been denominated κατ' ἐξοχην, *the Poet*, so the expression *Homeric beauties*, having passed into a proverb, has become amongst men of letters the appropriate qualification of the grand and the beautiful in poetry.

(Besides the works already quoted, see *Biographie Universelle*, art. HOMERE; Chalmers's *Biog. Dictionary*, art. HOMER; Blackwell's *Inquiry into the Life and Writings of Homer*, second edition, London, 1736, in 8vo; and Wood's *Essay on the Original Genius and Writings of Homer*, London, 1775, in 4to.) (A.)

HOMER, *Omer*, or *Chomer*, a Jewish measure, containing the tenth part of the ephah. See CORUS and MEASURE.

HOMICIDE signifies in general the taking away of the life of a human being. It is of three kinds; *justifiable*, *excusable*, and *felonious*. The first has no share of guilt at all; the second very little; but the third is the highest crime against the law of nature that man is capable of committing. See PENAL JURISPRUDENCE.

HOMILY, in ecclesiastical writers, a sermon or discourse upon some point of religion, delivered in a plain manner, so as to be easily understood by the common people. The word is Greek, ὁμιλια, formed from ὁμιλος, *cœtus*, assembly or council.

The Greek homily signified a familiar discourse, like the Latin *sermo;* and discourses delivered in the church took these denominations, to intimate that they were not harangues or matters of ostentation and flourish, like those of profane orators, but familiar and useful discourses, such as those of a master to his disciples, or of a father to his children.

All the homilies of the Greek and Latin fathers were composed by bishops. We have none of Tertullian, Clemens Alexandrinus, and many other learned persons, because, in the first ages, bishops alone were admitted to preach. The privilege was not ordinarily allowed to priests till towards the fifth century. St Chrysostom was the first presbyter who preached regularly. Origen and St Augustin also preached, but it was by a peculiar license or privilege.

Photius distinguishes a *homily* from a *sermon* by this, that the homily was performed in a more familiar manner, the prelate interrogating and talking to the people, and they in their turn answering and interrogating him, so that it was properly a conversation; whilst the sermon was delivered with more form, and in the pulpit, after the manner of the orators.

The practice of compiling homilies, which were to be committed to memory, and recited by ignorant or indolent priests, commenced towards the close of the eighth century, when Charlemagne ordered Paulus Diaconus and Alcuin to form homilies or discourses upon the Gospels and Epistles, from the ancient doctors of the church. This gave rise to the famous collection entitled the *Homilarium of Charlemagne*, which being followed as a model in many productions of the same kind, composed by private persons, from a principle of pious zeal, contributed much, according to Mosheim, to nourish the indolence and to perpetuate the ignorance of a worthless clergy.

There are still extant several fine homilies, composed by the ancient fathers, particularly by St Chrysostom and St Gregory.

Clementine HOMILIES, in *Ecclesiastical History*, are nineteen homilies in Greek, published by Cotelerius, with two letters prefixed; one of them written in the name of Peter, the other in the name of Clement, to James bishop of Jerusalem, in which last they are entitled Clement's Epitome of the Preaching and Travels of Peter. According to Leclerc, these homilies were composed by an Ebionite in the second century; but Montfoucon supposes that they were forged long after the age of Athanasius. Dr Lardner apprehends that the Clementine homilies were the original or first edition of the Recognitions; and that they are the same with the work censured by Eusebius under the title of Dialogues of Peter and Appian.

HOMOGENEOUS, or HOMOGENEAL (composed of the Greek words ὁμος, *like*, and γενος, *kind*), is a term applied to various subjects, to denote that they consist of similar parts, or of parts of the same nature and kind; in contradistinction to *heterogeneous*, where the parts are of different natures or kinds.

HOMOLOGATION, in the civil law, the act of confirming or rendering a thing more valid and solemn, by publication, repetition, or recognition thereof. The word comes from the Greek ὁμολογια, *consent* or *assent*, formed from ὁμος, *similis*, like, and λογος, from λεγειν, *dicere*, to say; that is, to say the same thing, to consent or agree.

HOMOLOGOUS, in *Geometry*, an appellation given to the corresponding sides and angles of similar figures.

HONDEKOOTER, MELCHIOR, a Dutch painter, born at Utrecht, who excelled in painting animals, and especially birds. His father and grandfather were of the same profession, and their subjects the same. He was trained to the art by his father; but surpassed him, and even the best of his contemporaries. Till he was seventeen years of age he continued under the direction of his father, and accustomed himself to paint different sorts of birds; but he took particular pleasure in representing cocks, hens, ducks, chickens, and peacocks, which he described in an elegant variety of actions and attitudes. After his father's death, which happened in 1653, he received some instructions from his uncle John Baptist Weeninx; but his principal and best instructor was nature, which he studied with intense application. His pencil was neat and delicate; his touch light; his colouring natural, lively, and transparent; and the feathers of his fowls were expressed with a swelling softness, which might have readily and agreeably deceived the eye of any spectator. It is reported that he had trained up a cock to stand in any attitude he wanted to describe, and that it was his custom to place that creature near his easel, so that at the motion of his hand the bird would fix itself in the proper posture, and would continue in that particular position without the smallest perceptible alteration for several hours at a time. The landscapes which he introduces as the backgrounds of his pictures are adapted with peculiar judgment and skill, and admirably finished; they harmonize with his subject, and always increase the force and the beauty of his principal objects. He was very happy in imitating the natural plumage of the fowls he painted; which not only produced a charming effect, but may also assist an intelligent observer in determining which are the genuine works of this master, and which the impositions. He died at Utrecht in 1695, aged fifty-nine.

HONDURAS, a settlement of Great Britain, in the southern part of the North American continent, and province of Yucutan. It is situated between the parallels of 17. and 19. north latitude, and 88. and 90. west longitude, on a peninsula which forms the Bay of Campeachy on the west and the Bay of Honduras on the east. Its name is derived from the Spanish term Hondura, which signifies depth, and was originally given to the coast by its discoverers, on account of the great depth of water along the shore. According to the best geographical authorities, the line which embraces this settlement commences at the mouth of the Rio Grande, or Hondo, whose course it at first follows, and afterwards runs parallel with it for thirty miles. It then turns south, and passes through the New River Lake, in a straight line, to the river Balize, up which it ascends for a considerable distance, till again bending in a southerly direction, it meets the head of the Libun, whose course it pursues to the sea. The whole settlement embraces an area of 62,750 square miles.

This coast was discovered by Columbus in the year 1502, but little that can be relied upon is known of its early settlement. The abundance and fine quality of the wood, particularly mahogany and logwood, seem first to have drawn attention to it; and at a pretty early period it was occasionally resorted to by wood-cutters. But the first permanent establishment of British wood-cutters was made at Cape Cartoche, by some adventurers from Jamaica, whose numbers increasing, they extended as far south as the river Balize, and as far west as the neighbourhood of Campeachy. The Spaniards, however, did not quietly submit to this usurpation of their territorial dominion. Several expeditions were fitted out against the settlers, but they were uniformly unsuccessful; and on two occasions, in 1659 and 1678, so complete was their discomfiture, that the town of Campeachy itself was taken by the logwood-cutters, with only the assistance of the seamen engaged in the trade. This last repulse occurred eight years after a treaty had been concluded with Spain, by which the territorial right of Britain to the occupancy of Honduras was generally, although not specifically, embraced. The successes of the settlers aroused the jealousy of the Spaniards, and led to a renewed discussion of their right to the territory which they occupied. This would appear to have been again generally admitted; but the Spaniards finally succeeded in driving the woodmen from the Campeachy shore, and confining them to the limits which we have already defined. An attempt was again made in 1718 to dispossess the British of the territory on the river Balize; but the firmness of the woodcutters deterred the Castilians from effecting any thing, except the erection of a fortification, which in a few years they abandoned. In 1754 an expedition was undertaken to exterminate the colony; but by a treaty of peace concluded in the year 1763, the Spaniards were compelled to admit the right of occupancy to the British colonists, which, however, they subsequently attempted to annul. In 1779 the Spaniards again attacked the settlement, and after destroying property to a considerable amount, they took a number of the colonists prisoners, and marched them off in irons to Merida, whence they were shipped to the Havannah, and there confined till 1782. In 1784 Britain obtained from Spain a specific grant of "the lands allotted for the cutting of logwood," by which Honduras became as much a territorial occupancy of the British crown, as Jamaica or any other of our colonial possessions. The last attack on the settlement was made during the war in 1798, but the expedition, which consisted of 3000 men, was gallantly repulsed; and since that period the colony has remained undisturbed by foreign aggression.

The coast of the Bay of Honduras is low, and the shore is studded with a number of low islands or keys, which, however, are verdant. As we recede from the coast, the land rises into a bold and lofty country, interspersed with rivers and lagoons, and covered with gigantic forests. The inland frontier is formed by an immense chain of mountains, which are also covered with impenetrable forests and brushwood. Through this rocky barrier there is only one pass, namely, that leading to Peten. It is merely a pathway, which might be defended by a few men. The lagoons or sheets of water, and the falls and rapids of the rivers, constitute sublime and beautiful features in the general aspect of the country. The river and lagoon of Manatee, which is situated ten leagues south of Balize, is considered as extremely grand. At about a mile from the mouth of the river is the lagoon, a magnificent sheet of water, extending for several leagues in a northerly direction. In many places immense mountains ascend from its margin, overtopping large valleys and wood ranges of great extent, where the tiger, antelope, armadillo, quash, opossum, racoon, and several species of deer, abound. Amongst the feathered tribes there are numbers of quails, plovers, pigeons, pheasants, and wild turkeys. The deficiency of streams amongst the mountain ridges is supplied by the presence of large marshy spots or shallow ponds, the banks of which are frequented by almost every species of water game. Fish abound during a great part of the year in these ponds, but the latter dry up in the season of drought, and then vast flocks of sea-fowl congregate around them to prey upon the fish which have been left dry by the evaporation of the waters. The alligator is also a frequent visitor; and, to partake of this repast thus yearly provided for him, he has been known to traverse trackless wilds, and make long journeys into the interior. Eight or ten miles from the lakes the rapids begin, and the high rocky banks of the river assume a romantic and beautiful appearance. Further on there is a cataract of about a quarter of a mile in length, and of considerable acclivity. A cluster of beautiful caves, through which the river winds its way, and beneath which the traveller must pass, is next reached. They have been described as equally singular and grand:—"These magnificent natural excavations of the mountains are semicircular at the entrance, and about five yards in diameter. Within the cave the arch rises to the height of a hundred feet, and leads to another low arch, which, being passed, a second cavern of large size opens, beyond which is a third with a circular orifice, through which the river enters. During the floods the mouths of the caverns are filled with water, which boils up with prodigious fury, and thus detains travellers many days before they can pass through the caves or tunnels. In the rainy season, as the water increases on the upper or inland sides of the mountains, the river forces its passage through the interstices and openings in its sides with tremendous noise, forming an indescribably grand cascade of from forty to fifty feet high, issuing from an hundred orifices."[1]

The country is technically divided into the Pine and the Cahoun ridges. The soil of the former has a substratum of loose reddish sand, and its indigenous products consist of those varieties of vegetation the assimilative powers of which are strong and perennial. Extensive prairies expand over this soil, and the pine, from which it derives its name, is extremely abundant. The soil of the Cahoun ridge consists of a deep loam, capable of growing every species of European as well as of tropical aliment. Its fertility occasions the growth of much brushwood, and it is covered with the wild cotton and other gigantic trees.

Fruits, spontaneously produced, are exceedingly abundant, and consist of oranges of excellent quality, shaddocks, limes, mangoes, melons, pine-apples, water-melons, avocato pears, cashew, cocoa-nuts, and many others. They are all found in the neighbourhood of Balize, but are sometimes brought in large quantities from more elevated plantations. The mahogany and logwood trees are at present the staples of Honduras. The former is found best in elevated situations; and growing generally solitary, it is discernible at a great distance, from the yellow hue of its foliage. It is cut down at about twelve feet from the ground, and when felled, the logs are dragged to the banks of the streams and floated down in rafts. It is said that the boughs and limbs afford the finest wood, but the size is principally looked to in Britain. The logwood is found in low swampy grounds, growing contiguous to fresh water creeks and lakes, on the edges of which the roots, the most valuable part of the wood, ramify. They are felled during the dry season, and carried off when the wet season has laid the ground under water. There is another valuable tree called the *pinus occidentalis*, which grows to the height of sixty feet, and covers many thousand acres of country. It contains an immense quantity of tar and turpentine, and might be turned to good account were the vexatious duties on colonial timber removed. The pine-wood is of course highly inflammable, and in this respect it is very valuable to the poor, who make torches of it. It likewise powerfully resists decay, and is in consequence much used by builders. The cahoun, or cohoon tree as it is pronounced, is valuable on account of an oil which it yields. This unctuous product, when unadulterated, is almost colourless, destitute of any disagreeable taste, and when burned as a lamp oil it emits a beautiful palish flame without smoke or smell. There are various other kinds of wood of beautiful vein and close texture, such as ironwood, clay-wood, rosewood, palmaletta, and the like. Amongst minerals, veins of fine marble and mountains of alabaster are known to exist. Several valuable specimens of crystals have been found, and gold has at various periods been detected; but no pains were ever taken to ascertain whence it proceeded. Labouring Creek, which lies on the Balize, about one hundred miles inland, is remarkable for the petrifying properties possessed by its waters. They have also a powerful cathartic effect on strangers, and when applied externally to an ulcer, have a healing property.

---

[1] "There are also magnificent caves in the river Libun, eight or ten days' journey from Balize; and some interesting caverns exist in the creeks or arms of the old river."

The country abounds with all kinds of animals fit for the food of man. Except in very rough weather, the supply of salt-water fish of excellent quality is abundant. The common green turtle, when in a healthy condition, is a staple commodity in the market. It is often five feet long, and weighs from 200 to 250 lbs.

Balize, the capital of the settlement, is divided into two parts by the river of the same name. The part of the town which is situated upon the south or right bank of the river, along the eastern edge of a point of land, is completely insulated by a canal on its western side, which runs across from a small arm of the sea, and bounds the town on its south side. The houses are about 500 in number, and are in general well built, spacious, and even elegant. They are for the most part constructed of wood, and raised ten feet from the ground. The two parts of the town are connected by a bridge, which was built in 1818. It is twenty feet in width, and its span is 220 feet. It is entirely constructed of wood, and is well secured by balustrades on each side. The streets of Balize are regular, running parallel north and south, and intersected by others. The main one runs in a north-easterly direction to the bridge from the government-house, which is situated on the south-east point or angle of the island on the right bank of the river, and bounded on the south and east by the sea. Behind the government-house is the church, on the east side of the main street. The whole town is embowered in groves and avenues of the cocoa-nut and tamarind trees. Fort George is situated about half a mile from the river, on a small low islet.

The climate in the neighbourhood of Balize is generally moist. July is the hottest and dryest month of the year, and then the maximum heat is 83°, the medium 82°, and the minimum 80° of Fahrenheit. The great heat, however, is tempered by the sea breezes, which almost constantly prevail. During the wet seasons the thermometer sinks to 60°, and the variation in the temperature is sometimes very great. But the climate is by no means unhealthy; indeed it is asserted in the Honduras Almanack that it is more favourable to European constitutions than any other climate under the tropics. Where temperance and regularity are observed, the average duration of human life will not be less in Honduras than it is in this country.

There are various classes of society in this settlement, including Europeans, coloured people, Indians, and Mosquito men. The blacks of Honduras are distinct from the aborigines of the country, being of African descent. In general they are inclined to indulge those low propensities which are exhibited in a state of barbarism. A few of them, either from national usage or other causes, show an utter aversion to spirituous liquors, but by far the greater proportion are guilty of the most beastly excesses in this respect. Having been derived from various regions, they still retain all their national peculiarities; and, to keep themselves distinct from every other tribe, each nation selects one individual, on whom the rest of his people bestow the title of king, and who exercises over them a certain degree of authority. The blacks, as a body, have upon the whole little intelligence, and their dulness of comprehension is remarkable. It is asserted, however, in the Honduras Almanack, the best authority on this point, that some of the blacks exhibit an originality of talent and a degree of mental activity little inferior to their European brethren. They are much attached to their country, and with a native of his own land a Honduras black will share his last plantain. The *coloured* population has resulted from the intercourse of Europeans with Africans or Indians. They of course, morally speaking, assume a medium status, and partake more or less of the qualities of black and white, according to their distance from either. The *Mosquito* shore men abound in the colony. They are remarkable for a fine muscular formation of body, but in their countenances they exhibit an utter destitution of intelligence, and their habits are most barbarous. They acknowledge the existence of a good and evil spirit; and the little power of thought which they possess is displayed in their conduct towards their deities. The good spirit is neglected, because, say they, his goodness is so great that nothing is to be feared from his wrath, whilst, on the other hand, the evil spirit is propitiated, in order to deprecate his malevolence. The whole wealth of a Mosquito man consists in his canoe, paddle, and harpoon. With these he satisfies the cravings of nature, and his grovelling nature asks for no more. The *Indians*, the real aborigines of the place, are a timid, inoffensive race, apparently more under the influence of instinct than of reason. They perform the most astonishing journeys through woods as trackless as the sea, and impervious to all but themselves, with infallible correctness of direction and amazing rapidity. Although free from vindictive or malicious propensities, they are addicted to drunkenness to an excessive degree.

In religious matters Honduras forms part of the bishopric of Jamaica, and facilities are afforded by the establishment for religious instruction. There is a well-endowed school attached to it, conducted on the Madras system, and the average daily attendance of children is above a hundred. There are likewise two mission schools, and considerable benefit has already been reaped from these institutions. Not one of the least is the change of sentiment which has taken place with regard to marriage. Only a few years back this ceremony was little regarded, and virtue and decency were absolutely despised. A better feeling, however, is now beginning to prevail, of which the legislature has taken advantage; and, for the encouragement of public morals, great facilities to the marriages of the lower orders of blacks have been afforded by recent laws and regulations. Petty larceny, and misdemeanours resulting from intemperance, frequently occur; but atrocious crimes are happily seldom perpetrated. In the mechanical arts the blacks display little or no ingenuity, but the coloured people, approaching nearer to the European standard of mind, are considerably above the negroes in this respect. In architectural designs, however, and other arts by which domestic comforts are enhanced, the whites alone are to be depended upon. Some years back the inhabitants of Honduras were content with stoccadoed huts of the most primitive construction, but now there are many large, commodious, and even elegant houses, particularly in Balize.

The grand authority of the settlement is a mixed legislative and executive power, designated the Magistrates of Honduras, by whom enactments are made; and these become laws to be enforced by the executive part of the government, after they have been sanctioned by the king's representative. The magistrates are in number seven, and annually elected by the inhabitants. In them the power is vested, and they conduct the whole public business of the colony, without receiving any remuneration for their services. The superintendent is of course a nominee of the crown of Great Britain.

The militia of Honduras, which is a thousand strong, consists of a brigade of artillery and a regiment of the line; there is likewise a local maritime force, the whole being under the command of the superintendent and his aides-de-camp and staff. The following table exhibits the revenue and expenditure of Honduras from 1807 till 1830.

	Revenue.	Expenditure.		Revenue.	Expenditure.
1807	£7,566	£8,291	1819	£15,967	£16,896
1808	6,005	5,170	1820	17,249	17,266
1809	6,829	6,066	1821	12,306	12,027
1810	9,523	9,604	1822	14,831	14,296
1811	8,643	8,981	1823	19,294	20,112
1812	6,590	6,312	1824	14,125	14,163
1813	5,438	5,548	1825	17,594	17,634
1814	5,474	5,629	1826	13,256	13,755
1815	12,944	12,527	1827	17,415	17,562
1816	10,672	9,276	1828	10,653	10,760
1817	8,168	8,838	1829	11,744	11,759
1818	16,501	18,193	1830	15,673	15,806
Total,	104,353	104,435	Total,	180,107	182,036

It will be perceived that the revenue of this colony has very materially increased, and it would still increase were the interest of this settlement more attended to at home. Its resources are very great, and were emigration properly encouraged, it would soon become of vast importance both in a political and in a commercial point of view, more especially as there are still uncultivated many thousand square miles of the richest soil. Trade is yet in its infancy, but the value of the imports in 1830 was L.234,379, and of the exports L.316,151, employing a shipping inwards of 13,918 tons, and outwards of 16,351 tons, independently of a large coasting trade, which is on the increase. The following table exhibits the quantities of the principal articles exported from 1824 to 1830.[1]

Years.	Mahogany.	Cedar.	Indigo.
	Feet.	Feet.	Lbs.
1824	5,573,819	2,493	199,867
1825	5,083,170	21,000	211,447
1826	6,385,589	30,171	358,552
1827	6,904,998	19,781	81,767
1828	5,466,806	...	1,610 leeroons.
1829	4,631,391	912	1,474 ......
1830	4,556,986	...	2,650 ......

Much discrepancy prevails amongst authorities relative to the numbers of the inhabitants. The following table exhibits the aggregate population of Honduras from 1823 to 1830.

Years.	White and Free Coloured.		Slaves.		Total.	
	Males.	Females.	Males.	Females.	Males.	Females.
1823	842	798	1654	814	2496	1612
1826	1896	891	1606	804	3502	1695
1829	1596	920	1329	798	2925	1718
1830	937	919	1347	680	2284	1599

It is almost superfluous to observe, that here, as in all our other colonies, the name of slave has ceased to designate a subject of the British empire. (R. R. R.)

HONE, a fine kind of stone, used for setting razors, pen-knives, and other cutting instruments.

HONEY, a sweet vegetable juice, collected by the bees from the flowers of various plants, and deposited in the cells of the honey-comb. See BEE.

HONFLEUR, a maritime city of France, in the arrondissement of Pont l'Eveque and department of Calvados. It is an ill-built town, situated on the Seine, opposite to Harfleur. There are four churches, 1027 houses, and 9780 inhabitants, who subsist partly by the fishery, and carry on some manufactures of vitriol, of alum, and of lace. The herring fishery is the most extensive. Before the Revolution it was the principal place for the Newfoundland fishery and for the colonial commerce. Long. 0. 3. E. Lat. 49. 17. N.

HONDSCHOOTE, a town of France, in the arrondissement of Dunkirk, in the department of the North. It stands on the canal leading from Bergues to Furnes, contains 539 houses, and 3168 inhabitants. It is remarkable on account of the battle fought there in 1793, when the Duke of York, with the combined armies, advanced to take possession of Dunkirk, and was defeated by the French under the command of General Houchard.

HONITON, a market-town of the hundred of Axminster, in the county of Devon, 159 miles from London. It consists of one long street, on the great road from the metropolis to Exeter. It has suffered by frequent fires, and good houses have been constructed instead of those which were burned. The parish church is half a mile from the town, but there is a chapel of ease within it. It is an ancient burgh, and still returns two members to parliament, who are chosen by about five hundred voters. It had formerly considerable trade in making serges, but that has of late years greatly declined. Some employment for females is provided, by making thread lace; and none is more highly esteemed than that which bears the name of this place. There is here a well-attended market on Saturday. The population amounted in 1801 to 2377, in 1811 to 2735, in 1821 to 3296, and in 1831 to 3509.

HONORIACI, in *Antiquity*, an order of soldiery under the eastern empire, who introduced the Goths, Vandals, Alani, Suevi, and other tribes, into Spain. Didymus and Verinianus, two brothers, had, with great vigilance and valour, defended the passages of the Pyrenees against the barbarians; but being at length killed, the emperor Constantius appointed to defend those passages the *honoriaci*, who, not contented with laying them open to all the nations of the north then ravaging the Gauls, actually joined the spoilers.

HONOUR, a testimony of esteem or submission, expressed by words, actions, and an exterior behaviour, by which we make known the veneration and respect we entertain for any one on account of his dignity or merit. The word *honour* is also used in general for the esteem due to virtue, glory, and reputation. It is further employed to signify virtue and probity themselves, and an exactness in performing whatever we have promised; and in this last sense we use the term *a man of honour*. But *honour* is more particularly applied to two different kinds of virtue; bravery in men and chastity in women. Virtue and Honour were deified amongst the ancient Greeks and Romans, and had a joint temple consecrated to them at Rome; but afterwards each of them had separate temples, which were so placed that no one could enter the temple of Honour without passing through that of Virtue; and by this the Romans were continually put in mind that virtue is the only direct path to true glory. Plutarch tells us, that the Romans, contrary to their usual custom, sacrificed to Honour uncovered; perhaps to denote, that wherever honour is, it wants no covering, but shows itself openly to the world.

---

[1] The tables given above, and much other information, have been derived from Mr Montgomery Martin's work on the British colonial possessions, to which the reader is referred for more minute details regarding this settlement.

Honour, or *Rank*. The degrees of honour which are observed in Britain may be comprehended under these two heads; *nobiles majores*, and *nobiles minores*. Those included under the first rank are, archbishops, dukes, marquisses, earls, viscounts, bishops, and barons, which are all distinguished by the respective ornaments of their escutcheons; and those of the second are baronets, knights, esquires, and gentlemen. There are some authors who pretend that baronets are the last under the first rank; and their reason is, because this honour is hereditary, and by patent, like that of the nobility.

Honours of War, in one sense, are stipulated terms, which are granted to a vanquished enemy, and by which he is permitted to march out of a town, from a camp or line of intrenchments, with all the pomp and circumstance of military array. In another sense, the honours of war mean the compliments which are paid to great personages or military characters, when they appear before a body of armed men. The former, however, is the most common acceptation; and with respect to it we may observe here, that it is extremely difficult to describe the honours of war specifically, as almost every thing depends on the general by whom a capitulation is granted. In some instances the troops of a besieged garrison are permitted to march out with arms shouldered, drums beating, colours flying, and all or part of their baggage; in others, they are only allowed to advance silently in front of their works, ground or pile their arms, face to the right, and return within their intrenchments. To give examples on a matter so plain must be altogether superfluous.

Military Honours. All armies salute crowned heads in the most respectful manner, drums beating a march, colours and standards dropping, and officers saluting. Their guards pay no compliment, except to the princes of the blood, and even that by courtesy, in the absence of crowned heads.

To the commander-in-chief the whole line turns out without arms, and the camp-guards beat a march, and salute. To generals of horse and foot, they beat a march, and salute; to lieutenant-generals, three ruffles, and salute; to major-generals, two ruffles, and salute; to brigadiers, rested arms, one ruffle, and salute; to colonels, rested arms, and no beating. Sentinels rest their arms to all field officers, and shoulder to every officer. All governors who are not general officers, in all places where they are governors, have one ruffle, with rested arms; but for those who have no commission as governors, no drum beats. Lieutenant-governors have the main-guard turned out to them with shouldered arms. The master-general of the ordnance has the same respect and honours paid to him as the generals of cavalry and infantry.

Honour-Point, in *Heraldry*, is that next above the centre of the escutcheon, dividing the upper part into two equal portions. See Heraldry.

HONOURABLE, a title conferred on the younger sons of earls and the sons of viscounts and barons; as also on such persons as have the king's commission, and upon those who enjoy places of trust and honour.

HOOD, Robin, a famous outlaw and deer-stealer, who chiefly harboured in Sherwood Forest in Nottinghamshire. He was a man of family, and played his pranks about the end of the twelfth century. He was famous for archery, and for his hospitable treatment of all travellers who came in the way; levying contributions on the rich, and relieving the poor. At last, having fallen sick, and requiring to have blood taken, he is said to have been betrayed and bled to death. He died in 1247, and was buried at Kirklees in Yorkshire, then a Benedictine monastery.

Hood, in *Falconry*, is a piece of leather, with which the head of a hawk, falcon, or the like, is covered. See Falconry.

Hood's *Island*, the most northerly of the Mendoza's islands, in the South Pacific Ocean, discovered in 1774 by Captain Cook. Long. 138. 52. W. Lat. 9. 26. S.

HOOGHLY, an extensive district in the province of Bengal, formerly called Saatgong, situated principally between the 21st and 22d degrees of north latitude, and extending a considerable distance along both sides of the river Hooghly. It is bounded on the north by the districts of Burdwan and Kishenagur, on the south by the sea, on the east by Jessore and the Sunderbunds, and on the west by Midnapoor. This district consists of low flat land, very fertile; but that part which is nearest to the sea is very thinly inhabited; it is called the Sunderbund, is swampy, covered with wood, and remarkably unhealthy. It is intersected in every direction by rivers and their branches, which afford great facilities for internal navigation; but these waters are unfortunately infested by gang-robbers or river pirates, who are a most ferocious banditti, robbing in gangs, and often using torture to extort from their victims the disclosure of their hidden treasures. Along the shores of the ocean salt of an excellent quality is manufactured on account of the government. Although this district is so near Calcutta, which affords a ready and constant market for its produce, the greater part of the country lies in a completely desert state, infested by alligators, tigers, and a countless variety of vermin and reptiles.

Hooghly, an ancient and formerly a large town in the province of Bengal, situated on the western bank of the Hooghly, nearly twenty-six miles above Calcutta, and supposed to have been founded by the Portuguese about the year 1538. During the Mogul government, it was a town of great consequence, being the port of the western arm of the Ganges, where the duties on merchandise are collected. It very soon drew away all the trade from Saatgong, which had been before the government port of Bengal. During the prevalence of the Portuguese dominion in India, Hooghly was fortified, and continued to flourish till the year 1632, when it was attacked by order of the emperor Shah Jehan, and, after a siege of three months and a half, was taken by the Mogul troops, a thousand of the Portuguese being killed, and four thousand four hundred men, women, and children taken prisoners. From this period Hooghly became the imperial port. All the officers of the government were ordered to remove thither, and it was placed under the jurisdiction of a special governor. In the year 1642, the English, and soon afterwards the Dutch, obtained the permission of the native government to erect factories. After this period, every encouragement was given to commerce; and Hooghly, which was called Bukhshy Bunder, became a great commercial emporium between Europe, Persia, Arabia, and India. In 1686 hostilities commenced between the English and the nabob. An action ensued, in which the nabob's troops were defeated; and at the same time the town of Hooghly was cannonaded, and five hundred houses burned. The result, however, was a disgraceful peace; an amicable arrangement was made by the military superintendent of the district. But in consequence of Calcutta being an open town, the agent and council retired to that place. Long. 88. 28. E. Lat. 22. 54. N.

Hooghly *River*, properly the Bhagirutty, a river of Bengal, formed by the junction of the two westernmost branches of the Ganges, the Cossimbazar, and the Jellinghy. This is the port of Calcutta, being the only branch of the Ganges that is navigated by large vessels; yet the entrance to the river is rendered extremely dangerous and difficult, by reason of numerous sand banks in it, which are frequently shifting. The shoals are very numerous where the Ganges is joined by the Roopmarain; and as this river directly faces the approach from the sea, whilst Hooghly turns to the right, it occasions the loss of many vessels, which are carried up the Roopmarain by the force of the tide. The spring-tides run up with great violence, advancing at the rate of fifteen miles an hour. This is what is called by the Europeans the Bore, which commences at Hooghly Point, where the river first contracts itself, and is perceptible above Hooghly town; and though the distance is above seventy miles, it traverses this space in about four hours, running along the opposite bank to the Calcutta side, whence it crosses at Chitpoor, about four miles above Fort William, and rushes with great violence past Barnagore, Duckinsore, &c., frequently oversetting boats and driving ships from their anchorage. At Calcutta it sometimes occasions an instantaneous rise of five feet. The tide does not rise more than thirty miles above Calcutta; and during the rainy season its influence is checked by the large body of water that comes down the river. The Hooghly contains several kinds of good fish, particularly the cockup, sable mangoe fish, and prawns; and it abounds also in crocodiles and sharks. It is about three quarters of a mile broad at Calcutta, and eight or ten miles wide at the mouth. It is only navigable for ships as high as the tide reaches, and the upper part of it is nearly dry during the hot season; yet there are few rivers that can boast of a more extensive commerce, all the towns belonging to European nations, and several others by the natives, standing on its banks. It is esteemed to be the most sacred branch of the Ganges by the Hindus, and it is on this account that those who cannot afford to bury their dead throw them into the Hooghly.

HOOK, in *Angling*. See Angling.

Hooks of a Ship, are all those forked timbers which are placed directly upon the keel, as well in her run as in her rake.

Can-Hooks, those which being made fast to the end of a rope with a noose, like that which brewers use to sling or carry their barrels on, are made use of for slings.

Foot-Hooks, in a ship, the same with futtocks.

Loof-Hooks, a tackle with two hooks, one to hitch into a cringle of the main or foresail, in the bolt-rope at the leech of the sail by the clew, and the other is to hitch into a strap, which is spliced to the chess-tree. Their use is to pull down the sail, and succour the tackles in a large sail and stiff gale, that all the stress may not bear upon the tack. It is also used when the tack is to be seized more secure, and to take off or put on a bonnet or drabler.

Hook Pins, in *Architecture*, are taper iron pins, only with a hook-head, to pin together the frame of a roof or floor.

HOOKAH, amongst the Arabs and other nations of the East, is a pipe of a singularly-complicated construction, through which tobacco is smoked. Out of a small vessel of a globular form, and nearly full of water, issue two tubes, one perpendicularly, on which is placed the tobacco, the other obliquely from the side of the vessel, and to that the person who smokes applies his mouth; and the smoke by this means being drawn through water, is cooled in its passage, and rendered more grateful. One takes a whiff, draws up a large quantity of smoke, puffs it out of his nose and mouth in a dense cloud, and passes the hookah to his neighbour; and thus it goes round the whole circle. The hookah is known and used throughout the East; but in those parts where the refinements of life prevail, every one has his hookah sacred to himself; and it is frequently an implement of a costly nature, being of silver, and set with precious stones. In the better kind, that tube which is applied to the mouth is very long and pliant; and for this reason it is termed the snake. People who use it in a luxurious manner fill the vessel through which the smoke is drawn with rose-water, and the fume thereby receives some of the fragrant quality of that liquid.

HOOKE, Robert, an eminent English mathematician and philosopher, was the son of John Hooke, minister of Freshwater, in the Isle of Wight, where he was born in 1635. He very early discovered a genius for mechanics, by making curious toys with great art and dexterity. He was educated under Dr Busby in Westminster school, where he not only acquired a competent share of Greek and Latin, together with an insight into Hebrew and some other oriental languages, but also made himself master of a considerable part of Euclid's *Elements*. About the year 1653, he went to Christ-Church, Oxford, and in 1655 was introduced to the Philosophical Society of that place, where, discovering his mechanical genius, he was first employed to assist Dr Willis in his operations in chemistry, and afterwards recommended to the honourable Robert Boyle, whom he served several years in the same capacity. About this time he was also instructed in astronomy by Dr Seth Ward, Savilian professor of that science; and henceforward he distinguished himself by many noble inventions and improvements of the mechanical kind. He invented several astronomical instruments, for making observations both at sea and land; and was particularly serviceable to Mr Boyle in completing the invention of the air-pump. Sir John Cutler having founded a mechanic school in 1664, he settled an annual stipend on Mr Hooke, intrusting the president, council, and fellows of the Royal Society to direct him with respect to the number and subjects of his lectures; and on the 11th of January 1665 he was elected by that society curator of experiments for life, with an additional salary. In 1666 he produced to the Royal Society a model for rebuilding the city of London, destroyed by fire, with which the society was well pleased; but although the lord mayor and aldermen preferred it to that of the city surveyor, it was not carried into execution. As the rebuilding of the city, according to the act of parliament, required an able person to let out the ground to the proprietors, Mr Hooke was appointed one of the surveyors; and in this employment he acquired most part of his estate. Mr Oldenburgh, secretary to the Royal Society, having died in 1677, Mr Hooke was appointed to supply his place, and began to take minutes at the meeting in October, but did not publish the Transactions. In the beginning of the year 1687, his brother's daughter, Mrs Grace Hooke, who had lived with him several years, died; and he was so affected with grief at her death, that he hardly ever recovered it, but was observed from that time to become less active, more melancholy, and even more cynical, than ever. At the same time, a chancery suit in which he was concerned with Sir John Cutler, on account of his salary for reading the Cutlerian Lectures, made him very uneasy, and increased his disorder. In 1691 he was employed in forming the plan of the hospital near Hoxton, founded by Robert Ask, alderman of London, who appointed Archbishop Tillotson one of his executors; and in December the same year, Hooke was created doctor of physic by a warrant from that prelate. In June 1696, the chancery suit with Sir John Cutler was determined in his favour, to his inexpressible satisfaction. In the same year an order was granted to him for repeating most of his experiments at the expense of the Royal Society, upon a promise of his finishing the accounts, observations, and deductions from them, and of perfecting the description of all the instruments contrived by him; but his increasing illness and general decay rendered him unable to perform the task. He continued some years in this wasting condition; and languishing till he was quite emaciated, he died on the 3d of March 1702, at his lodgings in Gresham College, and was buried in St Helen's Church, Bishopsgate Street.

In his person he exhibited but a mean appearance, being of short stature, crooked, pale, lean, and of a meagre aspect, with lank brown hair, which he wore very long, and hanging over his face. His temper was penurious, melancholy, mistrustful; and though possessed of great philosophical knowledge, he had so much ambition, that he would be thought the only man who could invent or discover. Hence it has been asserted by some that he frequently laid claim to the inventions and discoveries of others, whilst he boasted of many of his own which he never communicated. He wrote, 1. *Lectiones Cutlerianæ*, or Cutlerian Lectures; 2. *Micrographia*, or Descriptions of Minute Bodies made by Magnifying Glasses; 3. A Description of Helioscopes; 4. A Description of some Mechanical Improvements of Lamps and Water-poises, 4to; 5. Philosophical Collections. After his death were published, Posthumous Works, collected from his papers by Richard Waller, secretary to the Royal Society.

The following is a chronological view of the inventions to which he laid claim. It would be harsh to say, with regard to any of them, that he did not at least think himself an inventor; with respect to several, his priority is beyond dispute.

1656. Barometer, or weather-glass.

1657. A scapement, for maintaining the vibration of a pendulum; and not long afterwards the regulating or balance-spring for watches.

1658. The double-barrelled air-pump, and the conical pendulum. His first employment of the conical pendulum was not less ingenious and scientific than it was original. He employed it to represent the mutual gravitation of the planets; a fact which he had most systematically announced. He had shown, that a force, perfectly analogous to gravity on this earth, operated on the surface of the moon and of Jupiter. Considering the numerous round pits on the surface of the moon, surrounded with a sort of wall, and having a little eminence in the middle, as the production of volcanoes, he inferred that the ejected matter fell back again to the moon, as such matter falls back again to the earth. Seeing Jupiter surrounded with an atmosphere, which accompanied and therefore pressed on him, as our air presses on the earth, he inferred that it was the same kind of power that maintained the sun and other planets in a round form. He inferred a force to the sun from the circulation round him, calling it a *gravitation;* and said that it was not the earth which described the ellipse, but the centre of gravity of the earth and moon. He therefore made a conical pendulum, the tendency of which to a vertical position represented the gravitation to the sun, and which was projected at right angles to the vertical plane, and showed experimentally how the different proportions of the projectile and centripetal tendencies produced various degrees of eccentricity in the orbit. He then added another pendulum, describing a cone round the first, whilst this described a cone round the vertical line in order to see what point between them described the ellipse. The results of the experiment were intricate and unsatisfactory; but the thought was ingenious. He candidly acknowledged that he had not discovered the true law of gravitation which would produce the description of an ellipse round the focus, owing to his want of due mathematical knowledge; and therefore he left this investigation to his superiors. Sir Isaac Newton was the person who made the discovery, after having entertained the same notions of the forces which connected the bodies of the solar system, before he had any acquaintance with Dr Hooke, or knew of his speculations.

1660. The engine for cutting clock and watch wheels. The chief phenomena of capillary attraction. The freezing of water a fixed temperature.

1663. The method of supplying air to a diving bell. The number of vibrations made by a musical chord.

1664. His *Micrographia* was, by the council of the Royal Society, ordered to be printed. In that work there are many just notions respecting respiration, the composition of the atmosphere, and the nature of light, which were afterwards attributed as discoveries to Mayow and others, who, though we are far from supposing that they stole their discoveries from Dr Hooke, were certainly anticipated by him.

1666. A quadrant by reflection.

1667. The marine barometer, and the gage for sounding unfathomable depths.

1668. The measurement of a degree of the meridian, with a view to determine the figure of the earth, by means of a zenith sector.

1669. The fact of the *conservatio virium vivarum,* and that in all the productions and extinctions of motion, the accumulated forces were as the squares of the final or initial velocities. This doctrine he announced in all its generality and importance, deducing from it the consequences which John Bernoulli valued himself so highly upon, and which are the chief facts produced by Leibnitz in support of his doctrine of the forces of bodies in motion. But Hooke was perfectly aware of their entire correspondence with the Cartesian or common doctrine, and was one of the first in applying the celebrated 39th proposition of Newton's *Principia* to his former positions on this subject, as a mathematical demonstration of them.

1673. That the catenarian was the best form of an arch.

1674. Steam-engine on Newcomen's principle.

1679. That the air was the sole source of heat in burning; that combustion is the solution of the inflammable vapour in air; and that in this solution the air gives out its heat and light. That nitre explodes and causes bodies to burn without air, because it consists of this air accompanied by its heat and light in a condensed or solid state, and air supports flame because it contains the same ingredients as gunpowder, that is, a nitrous spirit; that this air dissolves something in the blood whilst it is exposed to it in the lungs in a very expanded surface, and, when saturated with it, can no longer support life nor flame, but in the act of solution produces animal heat; that the arterial and venal blood differ on account of this something being wanting in one of them.

1680. He first observed the secondary vibrations of elastic bodies, and their connection with harmonic sounds. A glass containing water, and excited by a fiddlestick, threw the water into undulations, which were square, hexagonal, octagonal, &c. showing that it made vibrations subordinate to the total vibration; and that the fundamental sound was accompanied by its octave, its twelfth, and so on.

1681. He exhibited musical tones by means of toothed wheels, whirled round and rubbed with a quill, which dropped from tooth to tooth, and produced tones proportioned to the frequency of the cracks or snaps.

Hooke.

1684. He read a paper before the Royal Society, in which he affirms, that some years before that period he had proposed a method of discoursing at a distance, not by sound, but by sight. He then proceeds to describe a very accurate and complete telegraph. But, some years previous to 1684, Amontons had not invented his telegraph; so that, though the Marquis of Worcester unquestionably gave the first hint of this instrument, Dr Hooke appears to have first brought it to a useful state.

To him also we are indebted for many other discoveries of lesser note; such as the wheel barometer, the universal joint, the manometer screw, divided quadrant, telescopic sights for astronomical instruments, representation of a muscular fibre by a chain of bladders, experiments showing the inflection of light, and its attraction for solid bodies, the curvilineal path of light through the atmosphere.

HOOKE, *Nathaniel*, author of an esteemed Roman history, and other performances. Of this learned person the earliest particulars to be met with are furnished by himself, in the following modest but manly address to the Earl of Oxford, dated 7th October 1722; "My Lord, the first time I had the honour to wait upon your lordship since your coming to London, your lordship had the goodness to ask me what way of life I was then engaged in; a certain *mauvaise honte* hindered me at that time from giving a direct answer. The truth is, my lord, I cannot be said at present to be in any form of life, but rather to live extempore. The late epidemical distemper seized me, I endeavoured to be rich, imagined for a while that I was, and am in some measure happy to find myself at this instant but just worth nothing. If your lordship, or any of your numerous friends, have need of a servant with the bare qualifications of being able to read and write, and to be honest, I shall gladly undertake any employments your lordship shall not think me unworthy of. I have been taught, my lord, that neither a man's natural pride, nor his self-love, is an equal judge of what is fit for him; and I shall endeavour to remember that it is not the short part we act, but the manner of our performance, which gains or loses us the applause of Him who is finally to decide of all human actions. My lord, I am just now employed in translating from the French a History of the Life of the late Archbishop of Cambray; and I was thinking to beg the honour of your lordship's name to protect a work which will have so much need of it. The original is not yet published. 'Tis written by the author of the Discourse upon Epic Poetry, in the new edition of Telemaque. As there are some passages in the book of a particular nature, I dare not solicit your lordship to grant me the favour I have mentioned, till you first have perused it. The whole is short, and pretty fairly transcribed. If your lordship could find a spare hour to look it over, I would wait upon your lordship with it, as it may possibly be no unpleasing entertainment. I should humbly ask your lordship's pardon for so long an address in a season of so much business. But when should I be able to find a time in which your lordship's goodness is not employed?" The translation here spoken of was afterwards printed in 12mo, 1723. From this period until his death, Mr Hooke enjoyed the confidence and patronage of men not less distinguished for virtue than for rank. In 1730 he published a translation of Ramsay's Travels of Cyrus, in 4to; in 1733 he revised a translation of the History of the Conquest of Mexico by the Spaniards, by Thomas Townsend, printed in two vols. 8vo; and in the same year he published, in 4to, the first volume of the Roman History, from the building of Rome to the ruin of the Commonwealth, illustrated with maps and other plates. In the dedication to this volume, Mr Hooke took the opportunity of "publicly testifying his just esteem for a worthy friend, to whom he had been long and much obliged," by telling Mr Pope, that the displaying of his name at the head of those sheets was "like the hanging out a splendid sign to catch the traveller's eye, and entice him to make trial of the entertainment the place affords. But," he proceeds, "when I can write under my sign, that Mr Pope has been here, and was content, who will question the goodness of the house?" The volume is introduced by Remarks on the History of the Seven Roman Kings, occasioned by Sir Isaac Newton's objections to the supposed 244 years' duration of the royal state of Rome. His nervous pen was next employed in digesting an account of the conduct of the Dowager-duchess of Marlborough, from her first coming to court to the year 1710, 8vo. His reward on this occasion was considerable, and the reputation he acquired by the performance much greater. The circumstances of this transaction are thus related by Dr Maty, in his Memoirs of Lord Chesterfield (vol. i. p. 116): "The relict of the great Duke of Marlborough being desirous of submitting to posterity her political conduct, as well as her lord's, applied to the Earl of Chesterfield for a proper person to receive her information, and put the memoirs of her life into a proper dress. Mr Hooke was recommended by him for that purpose. He accordingly waited upon the duchess, while she was still in bed, oppressed by the infirmities of age. But, knowing who he was, she immediately got herself lifted up, and continued speaking during six hours. She delivered to him, without any notes, her account in the most lively as well as the most connected manner. As she was not tired herself, she would have continued longer the business of this first sitting, had not she perceived that Mr Hooke was quite exhausted, and wanted refreshment as well as rest. So eager was she for the completion of the work, that she insisted upon Mr Hooke's not leaving her house till he had finished it. This was done in a short time; and her Grace was so well pleased with the performance, that she complimented the author with a present of L.5000, a sum which far exceeded his expectations. As soon as he was free, and permitted to quit the house of his benefactress, he hastened to the earl to thank him for his favour, and communicated to him his good fortune. The perturbation of mind he was under, occasioned by the strong sense of his obligation, plainly appeared in his stammering out his acknowledgments; and he who had succeeded so well as the interpreter of her Grace's sentiments, could scarcely utter his own." The second volume of his Roman History appeared in 1745, when Mr Hooke embraced the occasion of congratulating his worthy friend the Earl of Marchmont, on "that true glory, the consenting praise of the honest and the wise," which his lordship had so early acquired. To the second volume Mr Hooke added the Capitoline Marbles, or Consular Kalendars, an ancient Monument accidentally discovered at Rome in the year 1545, during the pontificate of Paul III. In 1758 Mr Hooke published, 1. Observations on the Answer of M. l'Abbé de Vertot to the Earl of Stanhope's Inquiry concerning the Senate of ancient Rome, dated December 1716; 2. A Dissertation upon the Constitution of the Roman Senate, 1743; 3. A Treatise on the Roman Senate, by Dr Conyers Middleton, 1747; 4. An Essay on the Roman Senate, by Dr Thomas Chapman, 1750, a work which he inscribed to Mr Speaker Onslow. The third volume of Mr Hooke's Roman History, to the end of the Gallic war, was printed under his inspection before his last illness, but did not appear till after his death, which happened in 1764. The fourth and last volume was published in 1771. An octavo edition of the whole work was afterwards given to the world.

HOOKER, *alias* VOWELL, JOHN, born in Exeter about the year 1524, was the second son of Robert Hooker, who in 1529 was mayor of that city. He was instructed in grammar by Dr Moreman, vicar of Menhinit in Cornwall, and thence removed to Oxford, but to what college is uncertain. Having left the university, he travelled through Germany, and resided some time at Cologne, where he kept exercises in law, and probably graduated. He then went to Strasburg, where he studied divinity under the famous Peter Martyr. Having returned to England, he soon afterwards visited France, intending to proceed to Spain and Italy; but he was prevented by a declaration of war. He therefore returned to England, and fixed his residence in his native city, where, having married, he was in 1554 elected chamberlain, being the first person who held that office, and in 1571 represented his fellow-citizens in parliament. He died in the year 1601, and was buried in the cathedral church at Exeter. He wrote, amongst other works, 1. Order and Usage of keeping Parliaments in Ireland; 2. The events of Comets or blazing stars, made upon the sight of the comet Pagonia, which appeared in November and December 1577; 3. An addition to the Chronicles of Ireland from 1546 to 1568, in the second volume of Holinshed's work; 4. A Description of the city of Exeter, and of the sundry assaults given to the same (Holinshed, *Chron.* vol. iii.); 5. A Book of Ensigns; 6. Translation of the History of the Conquest of Ireland, from the Latin of Giraldus Cambrensis (Holinshed, *Chron.* vol. ii.); 7. *Synopsis Chorographica*, or an historical record of the province of Devon, never printed.

HOOKER, *Richard*, a very eminent writer and divine, was born at Heavytree, near Exeter, in the year 1553. Some of his ancestors were mayors of that city, and he was nephew to John Hooker the historian. He was first supported by this uncle at the university of Oxford, with the addition of a small pension from Dr Jewel, bishop of Salisbury, who in 1561 got him admitted as one of the clerks of Corpus Christi College. In 1573 he was elected scholar. In 1577 he took the degree of master of arts, and was admitted a fellow the same year. In July 1579 he was appointed deputy professor of the Hebrew language; and in October the same year he was, for some trivial misdemeanour, expelled the college, but immediately restored. In 1581 he took holy orders; and being appointed to preach at St Paul's Cross, he went to London, where he was unfortunately drawn into an unhappy marriage with Joan Churchman, the daughter of his hostess. Having thus lost his fellowship, he continued in the utmost distress till the year 1584, when he was presented to the rectory of Drayton Beauchamp in Buckinghamshire. In this retirement he was visited by Mr Edwin Sandys and Mr George Cranmer, his former pupils. They found him, with a Horace in his hand, tending some sheep in the common field, his servant having been ordered home by his Xantippe. Mr Sandys's representation to his father, of his tutor's situation, procured the latter the mastership of the Temple. In this situation he met with considerable molestation from one Travers, lecturer of the Temple, and a bigoted puritan, who in the afternoon endeavoured to confute the doctrine delivered in the morning. From a situation so disagreeable he solicited Archbishop Whitgift to remove him to some country retirement, where he might prosecute his studies in tranquillity. Accordingly, in 1591 he obtained the rectory of Boscomb in Wiltshire, together with a prebend in the church of Salisbury, of which he was also made subdean. In 1594 he was presented to the rectory of Bishopsbourne in Kent, where he died in the year 1600. He was buried in his own parish church, where a monument was erected to his memory by William Cooper. His great work on Ecclesiastical Polity, first published in 1594, is a strenuous defence of the English establishment; but it is at the same time remarkable for its liberal views of civil government. In this respect it coincides nearly with the theory of Locke; and, indeed, Hoadley says that the author was "styled the father of the Whigs." Hooker is beyond all question one of the most dignified and eloquent of our early writers. "I know not," says Mr Hallam, in his *Constitutional History of England*, "whether any later writer has more admirably displayed the capacities of our language, or produced passages more worthy of comparison with the splendid monuments of antiquity." He was the author of several sermons and tracts. His life, by Isaac Walton, is well known. Dr Garden, bishop of Worcester, published his works in folio, with a life by himself, in 1662. This collection has been several times reprinted, both in folio and in octavo. The last edition, in three vols. 8vo, with Walton's life prefixed, was published in 1830.

HOOKERY, a town of Hindustan, in the province of Bejapoor. It is now greatly reduced, being a poor town, but still exhibits the remains of the magnificence which it formerly possessed when it was under the Mahommedan government. The last of the Mogul sovereigns died in 1643. It is fifty-five miles south-south-west from Merritch. Long. 74. 47. E. Lat. 16. 13. N.

HOOLAIVA, or HOLAIVA, one of the Hapaee islands, in the South Pacific Ocean, which was found in a state of nature when visited by Captain Cook in 1777. It is joined to Lefooga by a reef that is dry at low water; and is thirty miles north-north-east of Annamooka. Long. 185. 36. E. Lat. 19. 52. N.

HOOLE, JOHN, translator of the *Gierusalemme Liberata* of Tasso, was the son of Samuel Hoole, watchmaker, London, and born at Moorfields in 1727. Having received some elementary instruction from his uncle, a tailor in Grub Street, he was sent to a private school in Hertfordshire, kept by Bennet, the publisher of Roger Ascham's works, where he acquired a knowledge of the Latin and French languages, and some smattering of Greek. It was the wish of the father to bring up his son to his own trade of watchmaker, in which he had met with considerable success; but the shortsightedness of young Hoole proving an insuperable objection, he was, at the age of seventeen, placed as a clerk in the accountant's department in the East India House. About this time, having accompanied to the theatre his father, who had access behind the scenes, he contracted a fondness for the stage, which, if indulged, might have proved fatal to him, seeing he was entirely devoid of histrionic talents; but his attention having been diverted from this pursuit, he employed his leisure in improving himself in Latin, and in learning Italian, which he studied with the view of being able to read in the original the *Orlando Furioso* of Ariosto, of which, while a boy, he had become enamoured in the translation of Sir John Harrington. From admiring he soon proceeded to translate his favourite production; but after having made some progress in his task, he laid it aside for a time, in order to execute a translation of the *Gierusalemme Liberata*, which, accordingly, he commenced in 1758. In 1761 he printed a specimen, which appears to have met the approbation of his friends; for the whole was published in 1763, with a dedication to the queen, written by Dr Johnson. This translation is distinguished for cold correctness and elaborate elegance; but, in the transfusion, the essential spirit of poetry has in a great measure evaporated, leaving a residuum, the general character of which is insipidity. In 1773 Hoole published the first volume of his *Orlando Furioso*, which was favourably received by the public; but the further prosecution of the translation was interrupted by his receiving an appointment as auditor of accounts to the East India Company, an office which occupied much of his time and attention; nor did the whole make its appearance until 1783, when it was published in five vols. 8vo. In 1785 he wrote the life of his friend Mr Scott, the poet of Amwell, with whom he had become acquainted in 1757; in 1791 he published the Orlando reduced to twenty-four books, in two vols. 8vo; and, in 1792, he gave to the English public Tasso's juvenile production, *Rinaldo.* He also published, in three vols. 8vo, the dramas and other poems of Metastasio, his versions of which display more spirit and variety than his translations of Tasso and Ariosto, of which the chief characteristic is an uniform and monotonous smoothness of versification. He was also the author of several dramas, namely, *Cyrus*, which appeared in 1768, *Timanthes* in 1770, and *Cleonice* in 1775; but none of these had any success on the stage. Mr Hoole lived in habits of intimacy with Dr Johnson, whom he attended in his last illness; and died at Dorking on the 2d of August 1803, in the seventy-sixth year of his age. In his private character he was amiable and estimable; but though a man of taste and a good scholar, he had not the slightest pretension to poetical genius, though, from long practice, he had acquired considerable skill in the mechanical construction of verse. He had no kindred sympathies with the *mens divinior* of true poetry, and in his hands, accordingly, its finer spirit generally escaped. (A.)

HOOLY ONORE, a town of Hindustan, in the Mysore rajah's territories. The fort is of a square form, with towers at the angles, and two on each face. In 1792 this fort was taken by the British, and completely sacked and destroyed by the Mahrattas. Prior to this invasion the country was flourishing and well cultivated; but so dreadful was the havoc occasioned by the Mahrattas, that, according to the statement of one officer, every evening when the army encamped they could count ten villages in flames. It is a hundred and twenty-two miles northwest from Seringapatam. Long. 75. 41. E. Lat. 13. 44. N.

HOONGA-HAPAEE, and HONGATONGA, two small islands in the South Pacific Ocean, consisting of large uninhabitable rocks, seen at the distance of fifteen leagues. They are thirty and twenty-six miles north from Tongataboo.

HOOPER, JOHN, bishop of Worcester, and a martyr in the Protestant cause, was born in Somersetshire, and educated at Oxford, probably in Merton College. In 1518 he took the degree of bachelor of arts, and afterwards became a Cistertian monk; but at length, disliking his fraternity, he returned to Oxford, and there became infected with Lutheranism. In 1539 he was made chaplain and house-steward to Sir John Arundel, who afterwards suffered with the protector in the reign of Edward VI. But that very Catholic knight, as Wood calls him, discovering his chaplain to be a heretic, Hooper was obliged to leave the kingdom. After continuing some time in France, he returned to England, and lived with a gentleman called Seintlow; but being again discovered, he escaped in the habit of a sailor to Ireland, whence he embarked for the Continent, and fixed his abode in Switzerland. When King Edward came to the crown, Hooper returned once more to his native country. By his old patron Sir John Arundel's interest with the Earl of Warwick, he was consecrated Bishop of Gloucester in 1550; and two years after he was nominated to the see of Worcester, which he held *in commendam* with the former. But Queen Mary had scarcely ascended the throne, when Bishop Hooper was imprisoned, tried, and, not choosing to recant, condemned to the flames. He suffered death at Gloucester, on the 9th of February 1554, being then nearly sixty years of age. He was an avowed enemy to the church of Rome, and not perfectly reconciled to what he thought remnants of popery in the church of England. In the former reign he had been one of Bonner's accusers, a circumstance which sufficiently accounts for his being made one of Queen Mary's first victims. He was a person of good parts and learning.

HOOPER, *George*, an eminent English divine, was born at Grimley, Worcestershire, on the 18th of November 1640. Having been instructed in grammar and classical learning, first at St Paul's, and afterwards at Westminster School, where he was a king's scholar, he was thence elected, 1657, to Christ Church, Oxford, where he took his degrees at the regular periods, and distinguished himself by his knowledge in philosophy, mathematics, Greek and Roman antiquities, and the oriental languages. In 1677 he was appointed almoner to the Princess of Orange, and went over to Holland, where he resided about a year, and then returned. In 1680 he is said to have been offered the divinity professorship at Oxford, which, however, was conferred on Dr Jane. In 1685 he attended the Duke of Monmouth in the Tower, and had much free conversation with that unfortunate nobleman, to whom, in his last moments, Hooper administered the consolations of religion. In 1691 he succeeded Dr Sharp in the deanery of Canterbury; in 1698 he was appointed preceptor to the Duke of Gloucester; and in 1701 he was chosen prolocutor of the Lower House of Convocation. In May 1703 he was nominated to the bishopric of St Asaph; and in March following he was translated to the bishopric of Bath and Wells, over which he presided during the long period of twenty-three years and a half. Bishop Hooper died at Berkley, Somersetshire, whither he had been accustomed occasionally to retire, on the 6th of September 1727, in the eighty-seventh year of his age. Besides some sermons, he published several works in his lifetime, and left a number of manuscripts, some of which he permitted to be printed. The following is a catalogue of both, viz. 1. The Church of England free from the imputation of Popery, 1682; 2. Discussion of the Controversy between the Church of England and the Church of Rome, concerning the Infallible Guide; 3. The Parson's case under the Land-tax, 1689; 4. A Discourse concerning Lent, 1694; 5. A Calculation of the credibility of Human Testimony, *Phil. Trans.* for October 1699; 6. New Danger of Presbytery, 1737; 7. Marks of a Defenceless Cause; 8. A Narrative of the Proceedings of the Lower House of Convocation from February 1700 to June 1701; 9. De Valentinianorum Hæresi conjecturæ, quibus illius Origo ex Ægyptiaca Theologia deducitur, 1711; 10. An Inquiry into the State of the Ancient Measures, 1721; 11. De Patriarchæ Jacobi Benedictione Conjecturæ. Among the manuscripts above mentioned, are a Latin sermon, and a Latin tract on Divorce. A beautiful edition of the works of Hooper was printed at Oxford, 1757, in folio, under the superintendence of Dr Hunt, professor of Hebrew. (A.)

HOORN, a city of the Netherlands, in the province of North Holland, and the capital of a circle of its own name. It is situated on the Zuyder Zee, is surrounded with ancient walls, and has a good harbour, with docks, and accommodations for ship-building. It contains ten churches, 2640 houses, and (in 1834) 10,200 inhabitants. The district around it is celebrated for the quantity of cheese it produces, more than four million pounds having been exported in some years. It was the place where that mode of curing herrings which has contributed much to the wealth of the country, was first practised. It was the birthplace of the navigator Schouten, who discovered the southernmost cape of America, which still universally bears the name of his native city. It was taken by the English and Russians in September 1799, but was speedily abandoned, from being too far in advance of the line of operations. Long. 4. 54. E. Lat. 52. 38. N.

HOORN *Islands*, two islands in the South Pacific Ocean, discovered in the year 1616 by Le Maire and Schouten. They were afterwards seen by the navigator Maurelle in 1781. The natives are treacherous, and had well nigh succeeded in cutting off a trading vessel by which they were visited in 1801. They are encircled by a reef of rocks. Long. 171. 30. E. Lat. 15. S.

HOP, a plant of great importance in brewing. This plant was originally brought into England from the Netherlands in the year 1524. Hops are first mentioned in the English statute book in the year 1552, viz. in the 5th and 6th of Edward VI. c. 5. And by an act of parliament of the first year of James I. c. 18, it appears that hops were then produced in abundance in England.

HOPE is the desire of some good, attended with a belief of the possibility at least of obtaining it, and enlivened with joy, greater or less, according to the greater or less probability of our possessing the object of our hope.

Hope, *Sir Thomas, Bart.* lord advocate to King Charles I. The earliest progenitor of this celebrated person noticed by our genealogists is *John de Hoip*, who, they say, came from France in the retinue of Margaret, queen of King James V. His son *Edward Hoip* was a person of reputation in Edinburgh in the time of Mary; and being a great promoter of the Reformation, was chosen a commissioner to represent the city in the memorable parliament of 1560. He was father of *Henry Hoip* or *Hope*, a considerable merchant, who had by his wife Jaqueline de Tott, a Dutch woman, said by a contemporary to have some time kept a worsted shop in Edinburgh, two sons, *Henry* and *Thomas*. The former became ancestor of the great and opulent branch of the *Hopes*, long settled at Amsterdam. Thomas, the individual before us, after passing through his grammatical education, which he did with some applause, obtained the place of servitor or clerk to the eminent Mr (afterwards Sir) John Nicolson of Laswade, advocate, under whom were, in all probability, formed the elements of his after fortunes. The situation of clerk to a practising advocate of the Scottish bar is at this day of some consequence; it was then of more. Prior to the institution of the College of Justice in 1532, division of labour in the profession of the law was scarcely known; and in the *advocate*, or *procurator*, as he was indifferently called, were united at once the chamber counsel, the barrister, and the attorney. The legal skill and knowledge, however, which the institution of the College of Justice induced, gradually detached the business of an attorney; and by act of sederunt dated 13th July 1596, advocates' first clerks were empowered to act below the bar, exclusive of all third persons. The place was valuable on a higher ground; it was almost the only path to professional knowledge, and indeed the domestic nursery of the bar. Our ancient common law having, on the erection of the Court of Session, been superseded by the principles of the Roman jurisprudence, the Scottish bar was, till the union, or rather till our own day, generally prepared for at some one of the foreign colleges, of which those of France and Italy were the most frequented, until the lustre of the Cujacian school in the Low Countries, aiding the connection which arose between us and them at the Reformation, drew the student thither. A knowledge of *practice*, however, still remained to be acquired; but Edinburgh had not yet its chairs of law, nor had the bar sent forth its Craig, its Stair, or its Mackenzie; and, according to the principles of the papal tribunals, of whose spirit the Court of Session partook so largely at its institution, the deliberations of the court were in secret with shut doors; none were then admitted within except the judges and officers of court, and these were all sworn to secrecy. The chamber of a practising advocate was therefore sought by all who meant to make the law the object of their pursuit. In the situation of servitor to Mr Nicolson we find Hope in the year 1600, in which also he married Elizabeth, daughter of John Binning, Esq. of the old and wealthy house of Binning of Wallyford, county of Haddington. About the same time he was appointed solicitor for life, in all actions and causes touching the collection and receipt of new augmentations, with a salary of L.200 Scots per annum. This appointment was made "with advice and consent" of Mr John Preston of Barns, a lord of session, and afterwards president of that court, collector-general of the augmentations; who also, on the 10th of March 1599, resigned his seat as one of the commissaries of Edinburgh, in Hope's favour. The general assembly also nominated him solicitor to the church.

On the 7th of February 1605 he was admitted advocate; and on the 9th of April following, we find him "advocate-substitute" (that is, as we understand, substitute to the king's advocate, then Hamilton of Binning) in the prosecution before the justiciary, at the instance of James Libberton, servant to James, Lord Balmerino, president of the Court of Session, against certain individuals for an assault.

His next appearance was on the other side of the bar, in the famous case of the ministers, which, as it exemplifies much not only of Hope's character, but also of the sentiments of the time in regard both to religious and civil liberty, merits some attention.

In 1592 presbyterianism was established in Scotland by law, but much against the wish of the sovereign, who accordingly lent all his efforts to suppress it again, and to substitute in its stead the show and subordination of episcopacy. His first attack was directed against the general assembly (the convocation of the Scottish church), which, although its meeting "every yeir at the least, and oftener *pro re nata*, as occasion and necessity sall require," was expressly secured by statute of the above year, he prorogued twice successively, first on account of the accession, and then on pretence of adjusting the union. A third prorogation was issued, and, as if to declare that the power of calling the assembly was in the king, no time was fixed for its meeting. The royal designs being thus manifest, it became incumbent on the church, if it meant to maintain its liberties, now to make a stand. Accordingly nine presbyteries sent their representatives to Aberdeen on the 2d of July 1605, the day and place named in the former prorogation. When they had assembled, Straiton of Laurieston, the king's commissioner, presented them a letter from the privy council, which being addressed "to the brethren of the ministry, convened at their assembly in Aberdeen," they resolved should not be read till they were constituted. They proceeded accordingly to elect a moderator and clerk. They then took up the letter, when a messenger-at-arms, also from the privy council, entered, and charged them to dismiss under pain of rebellion. The church having, in constituting their meeting, asserted their right to a general assembly, were prepared to comply with the wish of the council, and only requested the king's commissioner to name a day and place for next assembly. On his refusal, the moderator appointed the assembly to meet again on the last Tuesday of September ensuing, and then dissolved the meeting with prayer. The conduct of the church on this occasion was worthy of a people who had their religious liberty secured to them by law, and was marked at once by zeal for the rights of the church and respect for the authority of the sovereign, by intrepidity and moderation; but no sooner was the king apprised of it, than he directed the parties to be proceeded against with all rigour. John Forbes, minister at Airfurd, the moderator, John Welsh, minister at Ayr, and four others, were therefore cited to appear before the privy council to answer for their conduct. They appeared accordingly, but respectfully declined the jurisdiction of the tribunal as incompetent. A new crime thus sprung into being; and Hamilton, the king's advocate, and his ready instrument on all occasions, thereupon brought a prosecution against the six ministers, under an act passed during the infamous administration of Arran in 1584, which declared that none should decline the judgment of the king or privy council, under the pain of treason. On the 10th of January 1606 the trial came on at Linlithgow, and the counsel chosen by the prisoners were, "Mr Thomas Gray and Mr Thomas Hoip, advocates," Craig and Oliphant having refused to plead in the cause, though it seems they had previously engaged to do so. Gray was a man of sincere affection to the cause, and of good skill in the law; but he had no great readiness of utterance. Hope had never before pleaded in that court. A formal plea was first put in and overruled. Hope then argued the case to the court; but all his arguments, able and conclusive though they were, and his courage, learning, and ingenuity in maintaining them, proved unavailing; the indictment was sustained, and the truth of the facts sent to the jury as their only province; for, according to the practice of that time, all the facts of the case were circumstantially stated in the indictment, with a view to limit the jury to the single point whether the facts were proved or not, their effect, if proved, being already settled by the authority of the court, which the juries of that period scarcely ever ventured to dispute. The jury by a majority, and after much tampering and undue influence, found all the defendants guilty of treason, and in September following they were banished the kingdom for life.

The next notice we have of Hope is in a letter from the council to the king, dated 24th June 1608, where Oliphant, Russel, King, and he, are mentioned as "the most learned and best experienced of their professioun;" and we find that he gradually entered on the largest professional practice of his time. His knowledge of tithes and church-law was particularly remarked, so that King Charles I., whose anxiety to recover the church property is well known, impressed with a sense of his value, immediately on his accession appointed him king's advocate, in conjunction with the aged Sir William Oliphant of Newton. The king also then knighted him; and the Court of Session, by act of sederunt dated 12th July 1626, passed at the king's request, allowed him to plead covered. The nature of this last act has been strangely misapprehended by some of our writers. The usual explanation is, that having *two* (Playfair, Sharp, and some other peerage writers, assert he had *three*) sons on the bench, the court indulged him with the privilege of pleading with his cap on like the judges; it being deemed indecorous, they say, that a father should stand uncovered before his sons. The truth is, however, that Hope had no son on the bench at this time, nor for six years afterwards; and the act of sederunt had an origin altogether different. From the institution of the College of Justice till this time, the king's advocate was a member, not only of the bar, but also of the bench. But in February 1626, Oliphant was removed from the bench, and a royal ordinance issued, that no officer of state should have an ordinary seat there. It was this ordinance which was the occasion of the act in question; and the intent and meaning of the act no doubt was to assert and establish the equality of the king's advocate with the bench. It was not long before Hope took occasion to vindicate his dignity in a more substantial way; for it appears that, on account of some expressions used by him at the bar, the judges thought fit to visit him with a public censure. This, however, was not to be endured by Hope; so on his application to the fountain of honour, a royal letter, of date 4th December 1626, was despatched to the judges, in which the king sharply reproved them for their want of respect, and desired that in future none in his high office should be rashly censured, without first acquainting the king therewith.

On the 11th of February 1628, Hope was created a baronet; and on Oliphant's death in April following, he obtained a patent of the office of sole advocate to the king and prince for life, with a pension of L.200 sterling yearly out of the crown rents; an allowance larger than that enjoyed by the judges, or than had previously been annexed to the office. Not being a lord of session, a letter from the king was then also transmitted to the judges to allow him to remain in court during its deliberations, "sua that he may heir and knaw such thingis as sall happin to occur that concernis his majesty," the deliberations of the court being at this time carried on with shut doors; and as they proved dilatory in the matter, the king despatched a peremptory order, dated 10th October 1628, to allow him to sit within the bar, and to remain in court during its deliberations, both, in fact, ancient privileges of the king's advocate. This they obeyed on the 19th of November 1628, taking Hope's oath "to keip the secreits of the house." In 1630 he received from the crown a gift of L.2000. In 1632 his eldest son was knighted, and made a lord of session; and the next year his second son likewise received the honour of knighthood.

It was in 1632 that Hope produced his Minor Practicks, or Observations on the Law, delivered by him to his son orally, it is said, at his mornings' toilet. It is distinguished for its legal learning, the breadth and boldness of its views, the acuteness of its remarks, and the subtilty of its distinctions. To this last quality of it, indeed, we are indebted for the sketch of its author by Dirleton, who characterises Hope as "juris nostri peritissimus, sed nimiæ et captiosæ subtilitatis." A more minute account of Hope is given by Mackenzie. His forte, says he, consisted in a wonderful power of invention, which supplied him with so great a multitude of topics that he commonly wanted time for their exposition. His course in debate was uniform, yet peculiar; for when he had propounded an argument or exception, he usually adduced the reason upon which it was founded, and if that appeared doubtful, then the reason of the reason, or the ultimate principle itself. The resources of rhetoric were not unknown to him, but it seemed as if they were unnecessary. Of the illustrious triumvirate who in the days of Hope, Nicholson, and Stuart, adorned the Scottish bar, Nicholson improved our eloquence, Hope the law itself.

It was he who, according to some, devised the irritant and resolutive clauses of entails; the one to annul the deed attempted to be granted, the other to dissolve and forfeit the right of the person making the attempt. He also devised the title by adjudication on an heir's feigned bond.

We are moreover told that he recommended to the lords of erection, or titulars of church lands, a mode of getting all the kirk livings back again, notwithstanding the act of parliament which annexed them for ever to the crown, by causing a wadset of the same to be taken, and declaring in the writs that his majesty was indebted in large sums of money, though indeed he owed none. To the exercise of Hope's ingenuity in this last case, however, a different criterion must be applied from any that can be used in the others, he being in the employment of his sovereign to obtain and secure the annexation. Burnet expressly says that "Sir Thomas Hope, a subtle lawyer, who was believed to understand the matter of church property beyond all the men of his profession, though in all respects he was a zealous puritan, was made the king's advocate, *on his undertaking to bring all the church lands back to the crown;* yet," adds the bishop, "he proceeded in the matter so slowly, that it was believed he acted in concert with the party that opposed it."

Hope's conduct was equally unprincipled in another respect. During the struggles between the king and the puritans, he was the adviser of both. The tumult at Edinburgh in 1637, the supplication to the privy council in 1638, the war against the king in 1639, and the convention of estates in 1643, were all known to and approved of by him; yet all this time he was the king's advocate, and by his flattering carriage, says Bishop Guthry, insinuated himself so far with his majesty, that notwithstanding information enough, his majesty consulted and was ruled by him in most of his affairs. On account of the benefits derived by them from his counsels, the Covenanters continued him in his office of king's advocate; his second son, Sir Thomas, who had commanded the *College of Justice troop* in their army against the king, they made a lord of session, and lord justice general of Scotland; and his sixth son, Sir James, they made governor-general of the mint, then an office of importance, to which they annexed an exclusive local jurisdiction, both civil and criminal. The king, on the other hand, appointed Hope to almost the only place then in his gift, namely, that of his commissioner to the general assembly, a place new to a commoner, and in which Hope, now giddy with the height to which he had been raised, carried himself proudly and extravagantly. He died in November 1646. (U. U. U.)

Hope *Island*, an island situated in the South Pacific Ocean, and discovered in 1772. It is not far from Ceram island. There are also two small islands of this name near the north-east coast of New Holland. Long. 214. 36. W. Lat. 15. 41. S.

HOPLITES, Hoplitæ (formed from ὁπλον, *armour*), in *Antiquity*, were such of the candidates at the Olympic and other sacred games as ran races in armour. One of the finest pieces of Parrhasius was a painting representing two hoplites; the one running, and seeming to sweat large drops, and the other laying down his arms, exhausted and out of breath.

HOPLITODROMOS (formed from ὁπλον, *armour*, and δϱεμω, *I run*), in the ancient gymnastic sports, a term applied to such persons as went through toilsome and robust exercises in complete armour.

HOPLOMACHI, 'Οπλομαχοι (composed of ὁπλον, *armour*, and μαχομαι, *I fight*), in *Antiquity*, were a species of gladiators who fought in armour; being either completely armed from head to foot, or provided only with a casque and cuirass.

HOPPER, a vessel in which seed-corn is carried during the time of sowing. The word is also used for the wooden trough in a mill, into which the corn is put to be ground.

HOR, a mountain or mountainous tract of Arabia Petræa, situated in that circuit which the Israelites took to the south and south-east of Edom in their way to the borders of Moab. On this mountain Aaron died. The inhabitants were called *Horites*. This tract was also denominated *Seir*.

HORÆA, in *Antiquity*, were solemn sacrifices, consisting of fruits and other products of the earth, offered in spring, summer, autumn, and winter, that heaven might grant mild and temperate weather. These, according to Meursius, were offered to the goddesses called 'Ωϱαι, or *Hours*, who, being three in number, attended upon the sun, presided over the four seasons of the year, and had divine honours paid them at Athens.

HORAPOLLO, or Horus Apollo, was, according to Suidas, a grammarian of Panoplus in Egypt, who taught first at Alexandria, and afterwards at Constantinople, under the reign of Theodosius, or about the year 380 of our era. But as there were several persons of this name, it is uncertain whether the grammarian of Panoplus, or some other Horus Apollo, was the author of the two books still extant, "concerning the hieroglyphics of the Egyptians," which Aldus first published in Greek, 1505, in folio. These books have often been republished since, with a Latin version and notes; but the best edition of them is that of Cornelius de Pauw, which appeared at Utrecht in the year 1727, in 4to. Fabricius is of opinion that the *Hieroglyphica* did not emanate from the grammarian of Panoplus, to whom indeed Suidas does not attribute it, but that it is the production of another Horus Apollo, who flourished about fifteen hundred years before Christ, and wrote upon hieroglyphics in the Egyptian language, and from whose work an abstract was afterwards made, and translated into the Greek language. And this much seems certain, that, whatever may have been the epoch of the original author, the two books of *Hieroglyphics* contain the substance of an older work, interspersed with the fancies and conceits of a later age, when the true import of many of the Egyptian symbols was no longer understood. These books, however, besides being exceedingly curious in themselves, have derived a new and unexpected interest from the discoveries of Dr Young and M. Champollion; and though the former somewhat hastily treated the explanations of Horus Apollo as mere puerilities, the latter showed, in a very satisfactory manner, that some of them at least were well founded, and susceptible of confirmation from the interpretation of the hieroglyphical texts on the monuments; in other words, assuming these explanations as correct, and combining such assumptions with the values of other characters ascertained by different means, he found that the whole led to results, the truth of which was either self-evident or demonstrable. At the same time, it cannot be disputed that, in the abridged Greek version, there are many absurdities that could never have had a place in the Egyptian original from which it was made, and which must therefore be regarded as the interpolations of an age when the knowledge of hieroglyphics had declined, and the values of the more recondite symbols, particularly the tropical and ænigmatical, had been lost. Besides, the analogies on which Horus Apollo endeavours to explain the original employment and secondary import of the signs, are, many of them, fanciful and remote, though sometimes ingenious; they proceed upon assumptions, the truth of which cannot now be ascertained, and which are occasionally too far fetched and ridiculous not to startle the most credulous. It is highly probable, indeed, that, in the course of ages, the primary analogies were forgotten; that, in practice, many of the signs were employed arbitrarily, without reference to their precise original import, whether kuriological or tropical, usage prevailing over strict principle; and that abbreviated forms, though possessing in use a known and determinate value, were no longer susceptible of being resolved and re-expanded into their original elements. But, with all these drawbacks, this abridgment is highly curious in itself, and, in several instances, has afforded a clue to explanations which, but for the assistance afforded by it, might never have been discovered. See the article Hieroglyphics, *passim*. (A.)

HORATII, three Roman brothers, who, under the reign of Tullus Hostilius, fought against the three Curiatii, belonging to the Alban army. Two of the Horatii were killed; but the third, by his address, successively slew the three wounded Curiatii, and by this victory rendered the city of Alba subject to the Romans.

HORATIUS, surnamed *Cocles*, from his losing an eye in combat, was nephew of the consul Horatius Pulvillus, and descended from one of the three brothers who fought against the Curiatii. Porsenna having laid siege to Rome, drove the Romans from Janiculum, and pursued them to the wooden bridge over the Tiber, which joined the city to Janiculum. Largius, Herminius, and Horatius Cocles, sustained the shock of the enemy at the bridge, and prevented them entering the city with the Romans; but Largius and Herminius having passed the bridge, Horatius Cocles was left alone, and repulsed the enemy till the bridge was broken down under him, when he threw himself armed into the

Tiber, swam across the river, and entered Rome in triumph.

HORATIUS Flaccus, Q. one of the most celebrated of the Roman lyric poets, who was born on the 8th of December, B. C. 65, and died at the age of fifty-seven, B. C. 8. He was the son of a freedman of Venusia, a small village on the confines of Apulia and Lucania. His father's employment seems to have been that of an auctioneer (*Sat.* i. 6, 86); but he possessed also a small landed property, which, however, he soon abandoned to proceed to Rome, where he had a better opportunity of attending to the education of his son. The studies of the young poet were directed by the most eminent scholars of which Rome could then boast, and amongst others by Orbillius Pupillus, a celebrated philosopher. Towards his twentieth year Horace followed the custom which was then prevalent amongst the young Romans, and proceeded to Athens with the view of studying under the philosophers which that city still produced. He seems first to have directed his attention to the doctrines of the Academic School, though he was afterwards captivated by the more congenial philosophy of the Epicureans; and the general complexion of his life seems to have been influenced by this predilection, though, towards its close, he seems to have leaned a little towards the sterner and nobler creed of the Porch. He does not, however, acknowledge himself as the partisan of any peculiar system (*Epist.* i. 1, 13), but, like most of the eminent Romans of his time, was of the Eclectic School, which pretended to be a selection of the more reasonable doctrines of all the others. The murder of Cæsar, and the disturbances which ensued (B. C. 43), interrupted the philosophical studies of Horace. His feelings led him to support the cause of freedom, and he became a tribune in the army of Brutus; but his conduct at the battle of Philippi, which he has himself characterised with equal candour and naïveté, showed that he was not qualified to distinguish himself in the career of arms. He took advantage of the amnesty which the conqueror found it politic to grant after this unsuccessful attempt at resistance, and returned to his native country, where he found little cause of satisfaction either in the political aspect of the times, or in the events which had taken place in his own family. The death of his father had left him to his own resources, and his small patrimony had been confiscated in consequence of the part which he had taken in public affairs. It was about this time that he seems first to have attracted notice by his poetical genius, and to have become acquainted with the poets Virgil and Varius. Through their interest he was introduced to Mæcenas and Augustus, who not only admitted him to their intimate friendship, but presented the poet with a small property in the country of the Sabines, where he spent the greater part of his life in the quiet enjoyment of rural happiness. Here he composed most of those works which have immortalized his name.

The works of Horace are of two kinds; lyric and didactic. To the first class belong the Odes, and in the latter we reckon the Satires and Epistles, which are often distinguished by the general name of *Sermones* or *Eclogæ.* (See Bentley, *Præfat. ed. Horat.*) Though Horace was only pursuing the path in which he had been preceded by Lucilius, still we must consider the appearance of his Satires as constituting a new era in this particular species of composition. The overthrow of the Roman republic, and the consequent check given to freedom of speech, the change which had taken place in political affairs, and the personal connection of the poet with Augustus, Mæcenas, and the other distinguished men of the emperor's court, may well be supposed to have been little calculated to produce a satire of the peculiar character and freedom of Lucilius. Satire of such a kind was not only impracticable, but would have been without interest and without effect from the change which had taken place in the modes of thinking amongst the Romans. Such a change could not escape the notice of a man so clear headed and well acquainted with the world as the poet; the acts of men around him seemed to him to be the result of folly, and in this ridiculous light he presents them before us in his Satires. The object which he had in view was not so much to lash with all the power of indignant virtue the crimes of mankind, and thereby to procure their amendment, as, by the employment of the most delicate irony, and by laughter and ridicule, to draw them to the path of virtue. It was in this way alone that he could hope to improve the character of his contemporaries. The Satires of Horace supply in some degree the absence of all pure Roman comedy, representative of their actual life and manners. They may be considered as a mirror, in which the details of private life, and the every-day transactions of the times, are faithfully reflected. The Epistles resemble the Satires in character, except that they teach more directly lessons of virtue and morality.

Horace was a poet in his philosophy, and a philosopher in his poetry. He viewed the one through the medium of the imagination, and attempered the other with the sober spirit of truth. His observation is intuitive and unerring, his ridicule keen but not envenomed; he laughs at human follies without attempting to depreciate or degrade human nature; his sarcasms, though cutting, are felt to be just as well as polished; and we recognise in him the Democritus of poetry, who employed ridicule as an instrument of correction, not of malice. Hence his writings, with which we are familiar from boyhood, carry with them attractions which are felt in every period of life, and in almost every rank of society. They charm alike by the harmony of the numbers, the purity of the diction, the correctness of the imagery, and the justness of the sentiments. They exhilarate the gay, and interest the serious, according to the nature of the subject upon which the poet exercises his power. Professing neither the precision of analysis, nor the copiousness of system, they possess advantages which analysis and system rarely attain. They exhibit human imperfections as these really are, and human excellence as it practically ought to be; they develope every principle of virtue in morals, and point out every modification of decorum in manners; they please without the glare of ornament, and instruct without the formality of precept. These exquisite compositions are the productions of a mind enlightened by study, and invigorated by observation; they are comprehensive, but not visionary; delicate, but not fastidious; in them sagacity is unwarped by prejudice, and generosity uncramped by suspicion. They are distinguished by diction always adapted to the sentiment, and by efforts nicely proportioned to the occasion. They exhibit elegance without affectation, sublimity without bombast, satire without buffoonery, philosophy without mysticism. Hence it is that the writings of Horace are more extensively read, more clearly understood, and more acutely relished, than those of almost any other ancient author; they are perfect models of their kind, and will pass down to the most distant posterity as among the most finished and faultless productions of the classic muse.

Numerous editions have been published of his works, but the best are those by Gesner, Lips. 1752, 1772; Bentley, Cantab. 1711; Doring, Lips. 1803; Fea, Rom. 1811; to which may be added the more recent editions of Wakefield, Hunter, and Mitscherlich. The first four books of the Odes have been translated into English verse by Wrangham (Lond. 1820), and the Satires and Epistles by Dunster (1712).

HORDE, in *Geography*, is used to signify a company or mass of wandering people, who have no settled habitation, but stroll about, dwelling in waggons or under tents, ready to shift their quarters as soon as the herbage and fruits are exhausted.

HORDICALIA, or Hordicidia, in *Antiquity*, a religious feast amongst the Romans, in which they sacrificed cattle large with young. This feast fell on the 15th of April, on which day they sacrificed thirty cows with calf to the goddess Tellus, or the Earth, part of them being immolated in the temple of Jupiter. The calves taken out of their bellies were burned to ashes, at first by the pontifices, but afterwards by the eldest of the vestal virgins.

HOREB, or Oreb, a mountain of Arabia Petræa, contiguous to Mount Sinai on the south, and the scene of many miraculous appearances.

HORISPOOR, a town of Hindustan, in the Sikh territories, in the province of Lahore, ninety-eight miles east-south-east from the city of Lahore. Long. 75. 27. E. Lat. 31. 30. N.

HORIZON, or Horison, in *Geography* and *Astronomy*, a great circle of the sphere, dividing the world into two parts or hemispheres; the one upper and visible, the other lower and hidden. The word is pure Greek, ὁριζων, which literally signifies bounding or terminating the sight, being formed from ὁριζω, *termino, definio*, to bound or limit. See Astronomy and Geography.

The horizon is either *rational* or *sensible*. The *rational, true*, or *astronomical horizon*, which is also called simply and absolutely *the horizon*, is a great circle of the sphere, the plane of which passes through the centre of the earth, and the poles of which are the zenith and nadir. It divides the sphere into two equal parts or hemispheres. The *sensible, visible*, or *apparent horizon*, is a lesser circle of the sphere, which divides the visible part of the sphere from the invisible. Its poles, too, are the zenith and nadir, consequently the *sensible horizon* is parallel to the *rational;* and it is cut at right angles, and into two equal parts, by the verticals. The sensible horizon is divided into *eastern* and *western*. The *eastern* or *ortive* horizon is that part of the horizon in which the heavenly bodies rise; the *western* or *occidual* horizon is that in which the stars set. The altitude or elevation of any point of the sphere is an arch of a vertical circle intercepted between it and the sensible horizon. By sensible horizon is also frequently meant a circle, which determines the segment of the surface of the earth, over which the eye can reach, and it is also called the *physical horizon*. In this sense we say, a spacious horizon, a narrow, scanty horizon, and so forth.

HORIZONTAL, something which relates to the horizon, or is taken in the horizon, or on a level with the horizon. Thus we say, a *horizontal plane*, a *horizontal line*, and the like.

Horizontal Dial is that which is drawn on a parallel to the horizon, having its gnomon or style elevated according to the altitude of the pole of the place for which it is designed. Horizontal dials are, of all others, the most simple and easy. The manner of describing them may be seen under the article Dialling.

Horizontal Line, in *Perspective*, is a right line drawn through the principal point, parallel to the horizon; or it is the intersection of the horizontal and perspective planes. See Perspective.

Horizontal Plane is that which is parallel to the horizon of the place, or nothing inclined thereto. The business of levelling is to find whether two points be in the horizontal plane, or how much is the deviation between them.

Horizontal Plane, in *Perspective*, is a plane parallel to the horizon, passing through the eye, and cutting the perspective plane at right angles.

Horizontal Range, or *Level Range*, of a piece of ordnance, is the line it describes when directed parallel to the horizon or horizontal line.

HORN, in *Physiology*, a hard substance growing on the heads of different animals, particularly the cloven-footed quadrupeds, and serving them both as weapons of offence and defence.

Horn is also a sort of musical instrument of the wind kind, which is chiefly used in hunting, to animate and bring together the dogs and the hunters. The term anciently was, *wind a horn*, all horns being in those times compassed; but since straight horns have come into fashion, they say *blow a horn*, and sometimes *sound a horn*.

The *French Horn* is merely a wreathed or contorted trumpet.

Horn Distemper, a disease incident to horned cattle, affecting the internal substance of the horn, commonly called the pith, which it insensibly wastes, leaving the horn hollow.

Horn-Work (*ouvrage à corne*), in fortification, an outwork composed of a front and two branches; the front consisting of two half bastions and a curtain. This work is of the nature of a crown-work, but smaller, and serves the same purposes. The use of horn-works, in general, is to occupy some rising grounds in advance of the principal fortification, the distance of which determines that of the horn-work; and they are placed either before the curtain or before the bastions, according to circumstances.

HORNBERG, a town of the duchy of Baden, in Germany, in the circle of Kinzig, the capital of a bailiwick of the same name, in the Black Forest, comprehending one town and thirteen villages, with 8350 inhabitants. The town is situated in a romantic vale, and contains 1225 individuals.

HORNBY, a market-town in the parish of Melling, of the hundred of Lonsdale, in the county of Lancaster, 249 miles from London. It is situated on the river Lyne, has a Gothic church with an octagonal tower, and near to it is an ancient castle, built by the Barons Monteagle. There is a good market held on Thursday. The population amounted in 1801 to 414, in 1811 to 420, in 1821 to 477, and in 1831 to 383.

HORNCASTLE, a town and parish of the county of Lincoln, in Lindsey Division, 136 miles from London. It stands on the river Bane, in a valley which at seasons is nearly overflowed. It was an ancient Roman station, and some of the walls constructed by the Romans are still visible. There is a medicinal spring near the town, but it is not much applied to. There is a good market, which is held on Saturday. A canal has been constructed, which connects the river Bane with the Witham. The population amounted in 1801 to 2015, in 1811 to 2622, in 1821 to 3058, and in 1831 to 3988.

HORNCHURCH, a town in the hundred of Romford, of the county of Essex, fourteen miles from London, the population of which amounted in 1801 to 1331, in 1811 to 1562, in 1821 to 1938, and in 1831 to 2186.

HORNE, George, an English prelate of considerable eminence, was born in the vicinity of Maidstone, in the county of Kent, in the year 1730. His father was rector of Otham; and having for some time acted in the capacity of tutor at Oxford, was well qualified to superintend the education of his son. However, that the latter might not be spoiled by too long a residence at home, he was, by the advice of a friend, sent, at the age of thirteen, to Maidstone school, where he continued under an eminent teacher for two years, and acquired some knowledge of oriental literature, particularly the Hebrew. In his fifteenth year he went to Oxford, where he laboured indefatigably to store his mind with almost every branch of useful learning, and resolved to make polite literature subservient to the knowledge and illustration of the Scriptures. He studied the Hebrew more attentively, and was exhorted to abandon the method of Buxtorf, encumbered as it is with the Masoretic punctuation. The rectitude of his conduct, and the vivacity of his conversation, gained him the esteem of every person with whom he was acquainted. In the year 1749 he was made bachelor of arts, and next year was elected to a fellowship in Magdalen College, without any solicitation upon his part.

About this time he became a proselyte to the mysteries of Hutchinsonianism, chiefly through the influence of Mr William Jones. At the age of nineteen, his mind was completely fettered by these doctrines, believing that it was the design of Sir Isaac Newton and Dr Clarke to subvert the theology of the Scriptures, and introduce the stoical *anima mundi* instead of the God of the Universe. Under the influence of such an infatuation, it is not astonishing that he should have endeavoured to discredit the system of Newton. He obtained the degree of master of arts in the year 1752, when he engaged in a controversy on the subject of the Cherubim. With a view to recommend the writings of Hutchinson, he published, A fair, candid, and impartial state of the case between Sir Isaac Newton and Mr Hutchinson, in which is shown, how far a system of physics is capable of mathematical demonstration; how far Sir Isaac's, as such a system, has that demonstration; and consequently, what regard Mr Hutchinson's claim may deserve to have paid it. In the year 1753 Mr Horne entered into holy orders, and acquired high reputation as a public speaker, his compositions being excellent, and his elocution graceful. Whilst preaching before the university, he introduced some of his peculiar notions, which again led him into controversy. A pamphlet made its appearance, entitled A Word to the Hutchinsonians; or, remarks on three extraordinary sermons lately preached before the university of Oxford, by Dr Patten, Mr Wetherell, and Mr Horne. To this our author replied in an Apology for certain gentlemen in the university of Oxford, aspersed in a late anonymous pamphlet. The vindication of the hint to the Hutchinsonians was supposed to be the production of Dr Kennicott, who afterwards became so famous for his labours in collating Hebrew manuscripts, and his valuable edition of the Hebrew Bible. Mr Horne was chosen proctor of the university in 1758; and, on the honourable termination of his authority, was created bachelor of divinity. When Mr, afterwards Dr Kennicott, gave to the world proposals for collating the text of the Hebrew Bible, for the purpose of correcting the original, and preparing for a new translation, Mr Horne became very much alarmed. He apprehended that the adoption of such a measure would overwhelm the sacred text with licentious criticism; and on this ground he published, in 1760, A View of Mr Kennicott's method of correcting the Hebrew text, with three queries formed thereon, and humbly submitted to the consideration of the learned and Christian world. But an acquaintance which thus began in hostility was afterwards converted into genuine friendship, which continued throughout the whole of life.

In 1764, Mr Horne was created doctor in divinity, although not as yet advanced to any conspicuous station. On the death of Dr Jenner, the president of Magdalen College, in the beginning of 1768, Dr Horne was appointed to succeed him in a post at once honourable and valuable; after which he exchanged a single for a married life. Next year he published Considerations on the Life and Death of St John the Baptist, being the substance of several sermons preached by him before the university. In 1771 he was chosen chaplain in ordinary to his majesty, which he held for ten years. In 1772, when a number of clergymen had formed the resolution of petitioning parliament for relief as to subscribing the liturgy and thirty-nine articles, Dr Horne determined, if possible, to defeat their object; and for this purpose he published Considerations on the projected Reformation of the Church of England, in a letter to Lord North.

He now set about finishing his greatest work, which had occupied his attention for almost twenty years. This was his Commentary on the Book of Psalms, which appeared in 1776, in two volumes quarto. It exhibits profound erudition and fervent piety, and will be perused with pleasure and advantage by every judge of merit. In the same year he was chosen vice-chancellor of the university, which he held till the end of the year 1780. On the publication of Dr Adam Smith's letter, containing an account of the death of Mr David Hume, Dr Horne publicly animadverted upon it, in A Letter to Adam Smith, LL.D. on the life, death, and philosophy of his friend David Hume, Esq. by one of the people called Christians. In 1779, Dr Horne published, in two volumes octavo, Discourses on various subjects and occasions, which have procured the approbation of all description of readers.

As vice-chancellor of the university he became acquainted with Lord North, to whose interest, joined with that of Lord Hawkesbury, he was in 1781 indebted for the deanery of Canterbury. His time was now divided between that city and Oxford; and the conscientious discharge of every part of his complex duty made him universally beloved. In 1784 he published Letters on Infidelity, similar to his reply to Dr Adam Smith. The books against which he levelled his ridicule are, An Apology for the Life and Writings of David Hume, Esq.; Hume's Dialogues on Natural Religion; an Essay on Suicide by the same author, and a treatise entitled Doubts of the Infidels. In the year 1790, when Dr Bagot was translated to the see of St Asaph, Dr Horne was appointed to succeed him in the see of Norwich. His last literary labours were, Observations on the case of the Protestant Dissenters with reference to the Corporation and Test Acts, 1790; and a Charge intended to have been delivered to the clergy of the diocese of Norwich, at his first visitation, 1791. When he was raised to the episcopal dignity, his health, always delicate, began rapidly to decline; but from the waters of Bath he received great relief, and to this place he repaired a third time in the harvest of 1791. On his way thither, however, he was seized with a stroke of palsy, and after languishing for a few weeks, he died at Bath, on the 17th of January 1792, in the sixty-second year of his age.

He was powerfully animated in his last moments by those hopes which spring from the promises of the gospel, and the inexpressible satisfaction of a well-spent life. His erudition was extensive, his piety sincere, and his life irreproachable. His charity, both of a public and private nature, was extensive; and if not in debt at the end of the year, he felt perfectly satisfied. His posthumous works are, Discourses on several Subjects and Occasions; a volume of Sermons; and, Cautions to the Readers of Mr Law.

HORNERS, those people whose business it is to prepare various utensils from the horns of cattle. The horners were a considerable fraternity in the city of London some centuries ago. In the reign of Edward II. they complained to parliament, that by foreigners buying up the horns in England, they were in danger of being ruined, and their business lost to the nation. For this reason was made the statute 6 Edward IV. by which the sale of horns to foreigners, excepting such as the horners refused, was prohibited; and the wardens had power granted them to search all the markets in London, and twenty-four miles round, and to inspect Stourbridge and Ely fairs, to prevent such practices, and to purchase horns at stated prices. But on plausible pretences this law was repealed in the reign of James I., and thereupon the old evil revived. The horners again applied to parliament, and King Edward's statute was renewed, excepting as to the inspection of the fairs, and still, it is believed, remains in force.

HORNING, in *Scotch Law*, a writing issuing under the king's signet, at the instance of a creditor against his debtor, commanding him, in the king's name, to pay or perform within a certain time, under pain of being declared rebel and put in prison.

HORNINGSHAM, a town of the hundred of Heytesbury, in the county of Wilts, 102 miles from London, in which manufactures of fine cloths are extensively carried on. The population amounted in 1801 to 1030, in 1811 to 1118, in 1821 to 1267, and in 1831 to 1323.

HORNSEY, a large village of the hundred of Ossulton, in the county of Middlesex, five miles north of London, on the ascent of a hill commanding a view over the city. It is one of those places in which the richer citizens have built their rural retreats. The New River winds in a pleasing manner through the lower parts of the parish. The population amounted in 1801 to 2716, in 1811 to 3349, in 1821 to 4122, and in 1831 to 4856.

HORNPIPE, a common instrument of music in Wales, consisting of a wooden pipe, with holes at stated distances, and a horn at each end; the one to collect the wind blown into it by the mouth, and the other to carry off the sound as modulated by the performer.

Hornpipe is also the name of an English air, probably derived from the above instrument. The measure of this air is triple time, with six crotchets in a bar, four of which are to be beat with the hand down, and two up.

HOROGRAPHY, the art of making or constructing dials, called also dialling, horologiography, gnomonica, sciatherica, photosciatherica, and so on.

HOROLOGIUM, Ὡρολογιον (composed of ὡρα, *hora*, time, hour, and λογος, *speech*, *discourse*), a common name amongst ancient writers for any instrument or machine for measuring the hours. (See Chronometer.)

Modern inventions and gradual improvements have given birth to some new terms, and annexed meanings to others totally different from those which they originally had. All chronometers which announced the hour by striking on a bell were called *clocks*. Thus we read of pocket-clocks, though nothing would seem more absurd than to suppose that a clock, according to the modern idea, should be carried in the pocket. In like manner, all clocks which did not strike the hour were called *watches* or *time-pieces;* and the different parts of a striking clock were distinguished by the watch part and the clock part; the former meaning that part which measures the time, and the latter the part which proclaims the hours. In the report of Sir Isaac Newton to the House of Commons in 1713, relative to the longitude act, he states the difficulties of ascertaining the longitude by means of a watch; yet it is obvious, from several circumstances, that his remarks were directly to be understood of a time-piece, regulated by a pendulum; for his objections are founded on the known properties of the pendulum, some of which differ essentially from the properties of the balance and spring. It is also to be remembered that all the attempts of Huygens for finding the longitude were by means of pendulum clocks which did not strike the hour, and which consequently, according to the language of the times, were called *watches*. At this time such machines for measuring time as were fixed in one place were called *clocks* if they struck the hour; if they did not strike the hour, they were called *time-pieces;* and when constructed with greater care, for a more accurate measure of time, they were called *regulators*. Some artists have affected to call such watches as were constructed for astronomical and nautical observations by the name of *time-pieces*, probably to intimate that they possess the advantages of those constructed with a pendulum.

HOROPTER, in *Optics*, is a right line drawn through the point where the two optic axes meet, and parallel to that which joins the centres of the two eyes, or the two pupils.

HOROSCOPE, in *Astrology*, the degree or point of the heavens rising above the eastern point of the horizon at any given time when a prediction is to be made of a future event, as, the fortune of a person then born, the success of a design then laid, the weather, and so on. The word is composed of ὡρα, *hora*, hour, and the verb σκοπεω, *video*, I behold. Such was at one time the infatuation concerning horoscopes, that Albertus Magnus, Cardan, and others, are said to have had the temerity to draw that of Jesus Christ.

Horoscope is also used for a scheme or figure of the twelve houses or signs of the zodiac, in which is marked the disposition of the heavens for any given time. Thus we say, to draw a horoscope, to construct a horoscope, and the like. *Calculating a nativity*, is when the life and fortune of a person are the subject of the prediction.

HORREA, in Roman antiquity, were public magazines of corn and salt beef, out of which the soldiers were furnished on their march along the military roads of the empire. *Horrea* was also the name given to their granaries.

HORROX, Jeremiah, an English astronomer, and the first who observed the passage of Venus over the sun's disc, was born at Toxteth, Lancashire, about 1619. Having acquired some grammatical learning at a school in the country, he was sent to Emmanuel College, Cambridge, where he spent some time in the ordinary routine of academical studies. About 1633 he began to turn his attention to astronomy, and spent some years, with little profit, in studying the writings of Lansbergius. In 1636, he became acquainted with Mr William Crabtree of Broughton, near Manchester, who was engaged in similar pursuits; and both occasionally consulted Mr Samuel Foster, professor of astronomy at Gresham College, London. Horrox, having thus obtained a companion in his studies, resumed them with fresh vigour; he laid aside Lansbergius, whose tables he found as erroneous as his hypotheses were inconsistent; and having procured books and astronomical instruments, he applied himself at once to the theory of the science, and to the observation of the heavens. But whilst thus full of hope and of promise, he was suddenly cut off, on the 3d of January 1641, soon after he had completed the twenty-second year of his age. A short time before his death he had completed his *Venus in Sole Visa*. This interesting phenomenon he had observed at Hoole, near Liverpool; but his observations did not appear till 1662, when Hevelius published them at Dantzig, with some of his own, under the title of *Mercurius in Sole visus Gedani anno* 1661, *Maij* 3, *cum aliis quibusdam rerum cœlestium observationibus rarisque phœnomenis; cui annexa est Venus in Sole pariter visa anno* 1639. Besides this work, he had commenced another, in which he proposed to refute the hypotheses of Lansbergius, and to draw up a new system of astronomy agreeably to celestial observations, but for the most part conformable to the Keplerian laws. Of the papers which Horrox left behind him, all that escaped destruction were published by Dr Wallis in 1673, under the title of *Opera Posthuma*. (A.)

HORROR strictly signifies such an excess of fear as makes a person tremble.

Horror of a Vacuum, was an imaginary principle amongst the ancient philosophers, to which they ascribed the ascent of water in pumps, and other similar phenomena, which are known to be occasioned by the simple weight or pressure of the atmosphere.

HORSE.

Introduction.

The Horse is a distinct genus belonging to the order of *Belluæ*, or large beasts, and in himself the most serviceable of all quadruped animals, as well as the swiftest of those brought under the dominion of man. Notwithstanding these high qualifications, ancient history informs us, that, in the primitive ages of the world, the ass was used in preference to him, not only as a mere beast of burthen, but for the purpose of conveying, from place to place, persons of the highest distinction. This, however, may be satisfactorily accounted for. Previously to the art of horsemanship being known, the ass, a superior race of animal perhaps to that generally found in Europe, was more easily managed than the horse, and better suited to the kind of food usually met with for his support. He was, in fact, found to answer every purpose of horses, until mankind increased in numbers and in wealth, when the complicated interests that were the result brought their services into use, and they were trained to the art of war. But another reason may be given for the late introduction of horses. Their use was interdicted by the Almighty in the early ages of the world, first, lest his favourite people, the Israelites, should be led to idolatry, by carrying on commerce with Egypt; secondly, by their dependence on a well appointed cavalry, they might cease to trust in the promised aid of Jehovah; and, thirdly, that they might not be tempted to extend their dominion by such means, and then, by mixing with idolatrous nations, cease in time to be that distinct and separate people which it was His intention they should be, and without which the prophecies relative to the Messiah could not be fully accomplished. Thus, in the Book of Psalms, the horse commonly appears only on the side of the enemies of God's people; and so entirely unaccustomed to the management of him were the Israelites, at the period of their signal defeat of the Philistines and other idolatrous nations, that David, their commander and king, caused the greater part of the horses of the cavalry prisoners to be cut down, from his ignorance of any use to which he could apply them. In the reign of Solomon, however, a cavalry force was established, but to no great extent.

In the infant state of all nations, indeed, we can readily account for the restrictive use of horses. A great deal of land that might be applied to the production of human food is requisite for their maintenance in all countries; and, in hot and sterile ones, the camel answered better, and was found ready at hand. It is true they were used in the armies of the ancient Greeks and Romans, which were not considered as complete without them. In Greece they were not so numerous; but in a war with the Italic Gauls, the Romans are said to have had no less than seventy thousand horses, and seven hundred thousand foot, to attack their formidable enemies.[1] The army of Xerxes, when reviewed by him at Dorsica in Thrace, after it had passed the Hellespont, is reported by Herodotus, contemporary with him, to have contained eighty thousand horse; but the judicious reader will be inclined to make considerable abatements from the boasted amount of that celebrated but ill-fated expedition, resting, as it does, entirely on the authority of Grecian writers, who represented facts in the light the most unfavourable to their enemies, and the most glorious to their own gallant countrymen.

As in the scale of excellence, the horse ranks first of all animals coming under the denomination of cattle, and, as Buffon justly says of him, "possesses, along with grandeur of stature, the greatest elegance and proportion of parts of all quadrupeds," it is not a matter of surprise, that, as an image of motive vigour, he should have been the subject of the chisel and the pencil of the first artists in the world, or that the description of him by the pen should have been not considered as unworthy the greatest writers of antiquity. But it is in his native simplicity, in those wild and extensive plains where he was originally produced; where he ranges without control, and riots in all the variety of luxurious nature, that we can form an adequate idea of this noble animal. It is here that he disdains the assistance of man, which only tends to servitude; and it is to a description of his release from this servitude, his regaining his natural liberty, that we are indebted for two of the finest similes of the immortal Greek and Roman epic bards. The return of Paris, with Hector, to the battle of Troy, is thus given in the sixth book of the Iliad:—

> "Ὡς δ' ὅτε τις στατὸς ἵππος, ἀκοστήσας ἐπὶ φάτνῃ,
> Δεσμὸν ἀποῤῥήξας θείῃ πεδίοιο κροαίνων,
> Εἰωθὼς λούεσθαι ἐϋῤῥεῖος ποταμοῖο,
> Κυδιόων· ὑψοῦ δὲ κάρη ἔχει, ἀμφὶ δὲ χαῖται
> Ὤμοις ἀΐσσονται· ὁ δ' ἀγλαΐηφι πεποιθὼς,
> Ῥίμφα ἑ γοῦνα φέρει μετά τ' ἤθεα καὶ νομὸν ἵππων."

And Virgil is considered to have even exceeded Homer, in that splendid passage in the eleventh book of the Æneid, where Turnus turning out fully accoutred for the fight, is compared to a horse that has just broken loose from his stall:—

> "Qualis, ubi abruptis fugit præsepia vinclis,
> Tandem liber equus, campoque potitus aperto,
> Aut ille in pastus armentaque tendit equarum,
> Aut, assuetus aquæ perfundi flumine noto,
> Emicat, arrectisque fremit cervicibus alte
> Luxurians; luduntque jubæ per colla, per armos."

It is impossible, at this distance of time, to fix upon the native country of the horse, as he has been found, in various forms, and of various sizes, in every region of the Old World. The difference in size is easily accounted for. The origin of all animals of the same species was doubtless the same in the beginning of time, and it is chiefly *climate* that has produced the change we perceive in them. Warmth being congenial to his constitution, and cold naturally injurious to him, he is produced in the most perfect form, and in the greatest vigour, when subject to the influence of the one, and not only diminutive, but misshapen and comparatively worthless, when exposed to the evils of the other. Buffon, however, is wrong in making the horse indigenous to Arabia, as is clearly proved by a reference to the Sacred Writings. In the reign of Saul, horse-breeding had not yet been introduced into Arabia; for, in a war with some of the Arabian nations, the Israelites got plunder in camels, sheep, and asses, but still no horses. Even at the time when Jerusalem was conquered and first destroyed by Nebuchadnezzar, Arabia appears to have been without horses, as the Tyrians brought theirs from Armenia. That the earliest available uses of the active powers of horses was adopted by the Egyptians, the same authority satisfies us; for we read in the third chapter of Genesis, that when Joseph carried his father's remains from Egypt to Canaan, "there went up with him both chariots and horsemen." One hundred and fifty years afterwards, the horse constituted the principal strength of the Egyptian army; Pharaoh having pursued the Israelites with "six hundred chosen chariots, and with all the chariots of Egypt." The earliest period now alluded to was 1650 years before the birth of Christ; and 1450 years before that event, the horse was so far naturalized in Greece, that the Olympic Games were instituted, including chariot and horse races.

---

[1] See Duncan's *Discourse on the Roman Art of War.*

The origin of the native horse of our own country is now merely a question of historical interest, the discussion of which would not lead to much practical benefit. That experiments, founded on the study of his nature and properties, which have from time to time been made to improve the breed, and bring the different varieties to the perfection in which we now find them, have succeeded, is best confirmed by the fact of the high estimation in which the horses of Great Britain are held in all parts of the civilized world; and it is not too much to assert, that, although the cold, humid, and variable nature of our climate is by no means favourable to the production of these animals *in their very best form*, we have, by great care, and after a lapse of nearly two centuries, by our attention to breeding, high feeding, and good grooming, with consequent development of the muscles, brought them to the highest state of perfection (with one exception[1]) of which their nature is susceptible. They may be classed under the following heads, and treated of individually, viz. the Race-Horse, thorough-bred and not thorough-bred; the Hunter; the Hackney, for various purposes; the Charger; the Troop-Horse; the Coach, Chariot, and Gig Horse; the Stage-coach and Post Horse; and the Draught or Cart Horse.

THE RACE-HORSE.

Although we may safely pronounce that the native-breed of English horses, however esteemed for other purposes, could not *race*, in the present acceptation of that word, yet it is equally obvious that they formed the parent stock of the renowned English racer. The first step to improve it by a cross with eastern blood, appears to have been taken by James the First, who gave the enormous sum (in those days) of L. 500 for an Arab stallion, which, however, the Duke of Newcastle, in his work on Horsemanship (great authority at that time), wrote down, on account, chiefly, of his comparatively diminutive size. At the Restoration, however, there appears to have been a tolerably good breed of horses in England, which Charles the Second improved by an importation of Barbs and Turks, whose blood was engrafted on the original stock, already very considerably ameliorated by the services of a stallion called Place's White Turk, imported by Oliver Cromwell's Master of the Horse, who bore that name; and afterwards by those of the Helmsley Turk, followed by Fairfax's Morocco Barb. The change was at this time so visible, that the Lord Harleigh of that day expressed his fears lest it might be carried to such an extreme as to extirpate the strong and useful horse, which, perhaps, the majority of his countrymen were well satisfied with before. In the latter end of Queen Anne's reign, however, the first great trump turned up, to secure future success. This was a stallion, called Darley's Arabian, purchased in the Levant, by a Yorkshire merchant of that name, although without any real attestation of his pedigree, or country. The prejudice against Arabians, and other eastern horses, the effect of the Duke of Newcastle's anathema against them, having now, for the most part, subsided, a good deal of their blood had been infused into the mares of that day, when another stallion, whose services were still more signal, accidentally made his appearance. We allude to the Godolphin Arabian, as he was called, purchased out of a cart in Paris, and consequently of uncertain caste, but evidently the horse of the Desert; who, as will be hereafter shewn, may be said to have won the game. Although at first thought so meanly of, as only to be used as a teazer, yet, fortunately for the Turf, he lived twenty years after his services became notorious (by the accident of his being the sire of a capital racer, out of a mare which the stallion to which he was teazer refused to cover), and, strange to say, no very superior race-horse has appeared in England, for many years, that cannot be traced to his blood. The success of this horse was much facilitated by the lucky coincidence of his arrival in England at a critical time, that is to say, when the stock from Darley's horse, and the several Arabs, Barbs, and Turks, together with the Royal Mares imported by Charles the Second, had been "crossed," as the term is, on each other; and had produced mares worthy to be the channel of imparting his own transcendant qualities to posterity. Taking it for granted, then, that the English race-horse is descended from Arabian, Turkish, and African (Barb) blood; and also taking into consideration the various peculiarities in the form and power of each of those kinds, requiring modification of shape, qualities, and action suited to the purposes for which they were intended, it cannot be denied, that a task of no ordinary difficulty was imposed on the English horse-breeders, and that they have executed that task with a masterly hand. If other countries furnished the blood, England has made the race-horse.

With the exception of one Eastern horse, called the Wellesley Arabian, the grandsire of a winner of the Oaks in 1826, also of Dandizette, who ran second for that stake in 1823, and one or two more good runners, the English Turf has benefited nothing, during the last half century, from the importation of foreign blood. The fact is, that having once gotten possession of the essential constitutional parts necessary to form the race-horse, and which will be described hereafter, we ourselves have, by a superior knowledge of the animal, and the means of availing ourselves of his capabilities, not only by rearing and training, but by riding him also, brought him to a pitch of excellence which will not admit of further improvement. Superior as is the air of the desert, which is said to be so free from vapours, that the brightest steel is not affected with rust, if exposed to it for a night, to that of our humid and ever-varying climate; and propitious as it must be to animals found, *as the horse was found*, in the greatest perfection when reared in it; yet were the finest Eastern horse that could be procured, brought to the starting-post at Newmarket, with the advantage of English training to-boot, he would have no chance at any weight, or for any distance, with even a second-rate English race-horse. It may not, however, be uninteresting to point out what are the essential racing points originally imparted to the horse of our own breed by these foreign stallions and mares, and without which they never would have arrived at any thing approaching the excellence which they have, for the last century, attained.

A good deal of pains has been taken to define the meaning of the term "blood," as applied to the horse called thorough-bred. Osmer, an old but accredited writer on the Horse, pronounced it to be a certain elegance of parts, derived from air, climate, and food, which, being suitable to the true natural conformation of the animal, enables him to perform extraordinary feats of activity and motion, coupled with great endurance of the highest bodily exertion; and hence the expression, "he shews a vast deal of blood," means nothing more than that he is a truly formed race-horse. Where, he asks, is the blood of the Ostrich, whose speed is so great, that it can "laugh at the horse

---

[1] The exception is the English cart-horse, as will be stated hereafter.

Race-Horse.

and his rider?" "If the good qualities of the race-horse," says he, "depend upon blood, we could not, as we often do, see one horse very good, and his own brother, with equal advantages of good keep and training, very bad." It was the opinion of this writer, that it has been to the folly of expecting, that what is termed high-blood, in the Eastern horses, unaccompanied with essential form, will produce a racer, so many failures in the attempt to breed race-horses have occurred; that the virtue of what racing men call "blood," has been too much insisted upon, not being sufficiently influenced by the fact, that it can never be considered as independent of form and matter. We conceive there is a great deal of truth in each of the foregoing observations. Blood cannot be considered independently of form and matter, inasmuch as the excellence of all horses must depend on the mechanism of their frames, which, if duly proportioned, and accompanied with superior internal, as well as external organization, gives them stride, pace, and endurance. The quickness of repeating this stride also, and the power of continuance, will depend upon vigour of muscle, capacity of chest, and strength of the constrained lungs. The result, then, of this argument is, that when we speak of some of the celebrated stallions of former days having transmitted the good properties of their blood, or high eastern descent, to the race-horses of the present time, we can only imply, that they have imparted that true formation of parts, that firmness of bone and sinew, and that general superior organization, competent to give facility of action; together with great powers of respiration, which will enable horses to last under the severest trials of their powers. In fact, their excellence is in a great manner mechanical. Were it not so indeed, did they not excel each other according to the degrees of difference in their form and shape, and all the constituent parts, full brothers and sisters would prove of equal goodness on the race-course, health and condition being on a par. But this is very far from being the case; and again, if it depended on blood, the same horse would run alike on every description of ground, which we know rarely happens; but of this we may be assured, that it is a superiority of muscular substance, united with justly proportioned shape, and not innate blood, which enables a horse to bear to be pressed, on any description of ground, still more so upon such as is severe, as several of our race-courses are.

Yet if there must be this elegance of form, these nice proportions in the limbs, or moving levers of the race-horse, how is it that so many of those called "cross-made," plain, and apparently disproportioned horses, possess the power or parts conducive to speed and action? If blood can be defined the peculiar elegance in the texture of the external parts, how happens it that several very ugly horses and mares have at all times distinguished themselves on the Turf? Are there certain occult causes, not discoverable to the eye, that produce this excellence to which the rules and laws of action appear to be opposed? On these points it may be observed, first, that the force and effect of muscular motion is nearly beyond our ken; and, secondly, such horses are really not misshapen, inasmuch as there are hidden virtues in the mechanism of their internal frames, which the eye cannot detect; and where deficient in one point, they are recompensed by additional powers in others. They possess the essential points, although not so elegantly displayed; and this, we believe, is the case with other animals than the horse; although, generally speaking, true symmetry in all is attended with corresponding excellence in their useful properties, and adaptation to the purposes of man.

Those persons who insist upon an innate quality in what is termed "blood," are led to believe that there is something in the *nature* of a thorough-bred horse, which enables him to struggle in a race far beyond his natural capabilities, and which is distinguished by the term "game." We do not think there is. We learn from experience that horses often allow themselves to be *beaten* by others which are inferior to them, from sheer ill temper; but their efforts to *win* a race, we consider to be merely limited by their physical powers, the effect of a proper arrangement of their parts; and that the operation of the mind, or spirit, has nothing at all to do with it. The hero at the Olympic Games had, and the champion of the British boxing ring may have had, feelings which, from the superiority of their nature, and the fact of their character, interest, and future happiness, being all involved in the event, might have induced them to struggle even to the very verge of life; but the same sense of honour, and the same spirit of emulation, cannot be ascribed to the race-horse. If his own acting powers be unequal to those of others opposed to him in the race, he yields to that superiority, although it must be admitted, that what are called sluggish horses will not try to exert themselves to the utmost, unless urged to it by the spur and whip; and others, when spurred and whipped, slacken, instead of increasing, their speed. The final result of this discussion then is, that when, as has been previously suggested, we speak of such horses as King Herod, Highflyer, or Eclipse, having transmitted their blood to the past and present generations of running horses, we can only admit that they have transmitted that true formation of parts necessary to enable them to run races at a prodigious rate of speed, and to endure the severity of training for them.

Although we have spoken in disparagement of horses of the East as racers, upon the same terms with those of our own breeding, we are willing to allow them the merit of being the parent stock of all our racing blood; as it is quite evident the indigenæ of our own country, or of those European ones which approximate to it, would never have produced the sort of race-horse now seen on the British Turf. The nature and character, indeed, of the horse of the Desert, are peculiarly adapted to an animal who, like the race-horse, is called upon to put its physical powers to the severest test to which nature, aided by art, can submit. In the first place, the Arabian horse possesses a firmness of leg and sinew unequalled by any other in the world. This excellence, which he owes to climate, arises from his having larger muscles and *smaller bone* than other horses have;—muscles and sinews being the sole powers of acting, and on them depend the lasting qualities of an animal going at the top of his speed. Bones being the weight to be lifted, serve only to extend the parts; and it is evident, that such as are small, but highly condensed, like those of the deer, and the horse of the Desert, are, by occupying less space, and containing less weight, more easily acted upon by muscular force, than such as are large and porous, and for a greater duration of time, without fatiguing the acting powers. But the excellence of the Arabian horse, or horse of the Desert, does not end with his highly condensed bone, and flat and wiry leg, so much esteemed by the sportsman. All the muscles and fibres of his frame are driven into closer contact than those of any other breed; and, by the membranes and ligaments being composed of a finer and thinner substance, he possesses the rare quality of union of strength with lightness, so essential to the endurance of fatigue in all quick motions. He thus moves quicker and with more force, by reason of the lightness and solidity of the materials of which his frame is composed; and when to these qualifications are added the peculiar and deer-like elegance of his form, and extraordinary share of muscular power for his inches, he appears to furnish all the requisites of the race-horse on a small scale.

We have already accounted for the present breed of English race-horses being no longer susceptible of improvement from any foreign blood. But it is worth inquiring into the reason of the improvement of the horse of the Desert, and indeed of all the countries of the East, not advancing towards perfection, as that of our own breed has done. No doubt it was intended that we should improve upon animal nature, as we improve our own, and nowhere has the attempt been so successful as upon our varieties of domestic cattle; but the horse of the Desert now, if he have not retrograded in his good qualities, is the same animal that he was nearly two centuries back. With the exception of the Wellesley Arabian, said to have been bred in Persia (but the assertion is unaccompanied by proof), who measured fifteen hands two inches high, all the rest that have been imported have been little better than Galloways, which must be attributed to two causes; first, the want of being forced, as our own horses are, in their colthood, by high keep; and, secondly, by adhering too closely to the indigenous breed, or that whose blood is unmixed, by which means it has dwindled. Accurate observers must have noticed, that the greater part of the horses brought to this country as Barbs and Arabians, have exhibited a palpable deficiency in the points contributing to strength, and the want of general substance is apparent at first sight. It is true that, of late years, their estimation has so diminished in this country, that no great pains have been taken to procure stallions of the highest caste, and scarcely any mares have been imported; and several of those sent over have been accompanied by very unsatisfactory pedigrees. We are, however, inclined to think that, as the immediate descendants of such horses are found quite inefficient as race-horses, and but few of the second or third generation have turned up trumps, unless as a rational experiment, the breeding of *race-horses* from Arabians is at an end.

In corroboration, however, of the good qualities of form and texture of this comparatively Lilliputian breed, we give the following extract from a letter of the late Captain Gwatkin, head of one of the Honourable India Company's studs, on the subject of crossing the English thorough-bred horse with foreign blood, dated Hauper, Bengal, September 1828, to shew, by their rate of going, their great endurance under the combined pressure of weight and speed; for to have run these lengths in the time specified, their height only averaging fourteen hands one inch, and of course unfavourable to speed, in addition to the ground being sandy, and therefore void of elasticity, the pace must have been severe from end to end of the course. Unfortunately the ages are not given, or a still better judgment would be formed of the lasting powers of these little animals under more than average weight.[1]

Run at Bengal.

	Name.	Weight.		Time.		Distance.
		st.	lb.	m.	s.	
	Patrician	9	0	5	34	280 yards, less 3 miles.

We have reason to believe, that the best use to be made of Eastern horses, would be for the production of the English hunter, by the best-shaped hunting mares, nearly thorough-bred. By the help of the dam, and our present improved system of keeping young horse-stock, there would be little fear of the produce not coming to a good size, even in the first generation, as it is, for the most part, the property of these horses to beget stock larger than themselves; but by crossing the female produce in the second with our large thorough-bred horses, hunters for heavy weights might be looked for, with every prospect of success. We know that the virtue of the blood, or constituent parts, of the horse that was no racer (Marske, the sire of Eclipse, for example) has produced a racing son, by acquiring proper formation of parts from the dam; and if to the fine form of the English hunter, could be added the firmness of leg and sinew for which the Eastern horse is so conspicuous, but in which the English hunter is too often deficient, in conjunction with the larger muscles, more highly condensed bone, and well-known powers of endurance of the Eastern horse, not omitting his action, which is generally first-rate, but of which a proper judgment could be formed previously to the choice of the stallion, a great improvement upon our present race of hunters would be effected; and all such as were known to be thus bred, would meet a ready sale. It is a well known fact, that some of the most brilliant hunters England ever produced, were got by Arabian stallions; and one, by Lord Clive's Arabian, was decidedly the best horse in Leicestershire, in Mr Meynell's day, over every description of country. He was the property of the late Mr Childe, of Kinlet Hall, Shropshire, who is said to have been the first to introduce the present very spirited style of riding after hounds. A powerful Toorkoman stallion would not, we think, fail in getting hunters out of good English mares. That breed is the largest of any of the Eastern horses, owing to being reared on better land.

One word more on the subject of the Eastern horse, as connected with the English Turf. Owing to the doubts and uncertainties that hang over the pedigrees and countries of the most celebrated stallions and mares which laid the foundation of our present breed of racers, it is impossible to determine to which individual breed, whether to the Turkish, the Barb, the Arabian, or the Persian, are the greater advantages derived from them to be attributed. They appear to us to be pretty equally divided. To the Byerly Turk we are indebted for the Herod blood (sire of Highflyer); to the Godolphin Arabian, said to be a Barb, for the Matchem blood, the stoutest of any; to the Darley Arabian (the sire of Flying Childers), for the Eclipse blood; and to the Wellesley Arabian, believed to be a Persian horse, to the only real advantage gained to English race-

Race-Horse.

horses, by a foreign cross, in later years. It must, however, be observed, that the most famous horses of the last century, such as Childers, Old Crab, Eclipse, and King Herod, did not appear on the Turf before they were five years old; which leads us to suppose, that the failure of horses subsequently bred, as they themselves were bred, from Oriental blood, and trained at an early age, may, in great part, be attributed to the fact, of the immediate produce of such horses requiring more time to come to maturity, or even to a certain degree of maturity, than those, like our present breed of race-horses, further removed from such blood; and the cause may be attributed to climate. It is reasonable to suppose, that the produce of stallions and mares bred in the Torrid Zone, would come slower to perfection in a damper and colder country than it would have done in its own; and we may infer from this, that, in proportion as horses were brought earlier to the post, and races shortened in distance, Eastern blood got into disrepute.

Breeding the Race-Horse.

Amongst the many things in the history of Ancient Greece that have called forth the admiration of mankind, the celebrated games of Olympia claim the foremost place. Independently of their religious association, and advancement of literary spirit, they were highly serviceable to the country; and none proved more so than those at which horse-racing was introduced, which appear to have been completely established in the twenty-fifth Olympiad. That the improvement of the native breed of horses was the chief object of the government, is beyond all doubt, as it has been that of all others who have given encouragement to racing; and it is equally apparent, that the Thessalian courser, so highly extolled by Pindar, and likewise so terrible in war, was the result of a foreign cross. So essential, indeed, was this object considered in Greece, where horses were very scarce even after the time of Pindar, that it is stated, on the authority of Aretius, in a note on Pindar's second Isthmian Ode, that there was a general law in Greece, requiring all, who were able, to breed horses. As to what state of perfection their horses were bred in at this early period, is beyond the power of conjecture; but in Great Britain, from the highly cultivated knowledge of the mechanical structure of living bodies, with the junction of best shapes, although but for the stimulus given by racing, this knowledge would have been comparatively in its infancy, the horse has arrived at the highest state of perfection of which his nature is capable; and in whatever country, and in whatever climate, his racing powers are put to the test, he has scarcely found a rival, excepting under very disadvantageous circumstances. It is true his *lasting* qualities were doubted, and he was challenged to rebut the charge; and the following was the result. On the 4th of August 1825, two second-rate English racers, Sharper and Mina, contended against the most celebrated Cossack horses from the Don, the Black Sea, and the Ural, in a race of the cruel length of forty-seven miles. At starting, Sharper and Mina ran away with their riders more than a mile, and up a steep hill, when the latter horse broke down, and pulled up. Half the distance was run in an hour and forty minutes. In the last half, only one of the Cossack horses was able to contend with Sharper, who, notwithstanding every foul advantage was taken by changing the weight, and dragging along his opponent by a rope, won his race in gallant style, performing the distance in two hours and forty-eight minutes. At starting, the English horses carried three stone more weight than the Cossacks; and, during the latter half of the race, the one Cossack who remained in it was ridden by a mere child.

From the great export trade to the Continent of English horses, and particularly those of full blood, joined to the low price of horse-food during the last twenty years, and on which there is not much prospect of an advance, occupiers of land cannot turn their attention to a much surer source of profit than that of breeding horses, provided they go judiciously to work. But, unfortunately for the speculators in this branch of rural economics, too much is left to chance and experiment, and thus horse-breeding becomes absolutely a matter of speculation, instead of a matter of judgment. It is true, those noblemen and gentlemen whose studs have become eminent on the Turf cannot be included in this charge; but even with the benefit of great experience, and various other advantages, the utmost exercise of their judgment is required, to insure even a prospect of success against such a field as they have to contend with. Having said this, we will lay down a few practical rules for breeding and rearing the various kinds of horses now used in Great Britain, commencing, as before stated, with that of the Race-Horse.

In the first place, it may be observed, there has been a great deal of discussion in various publications on Sporting, but to very little purpose, on the much agitated question, "What constitutes full blood, or, what is termed, a thorough-bred horse?" We consider this question as very easily decided; the term "thorough-bred horse" merely implying one that can be traced through the Stud-Book, by sire and dam, to any Eastern stallion, or to what were called the Royal Mares, imported by Charles the Second, as they, together with two or three of the first imported stallions, form the *ne plus ultra* of all racing pedigrees. As to the assertion, that, for a horse to claim the title of thorough-bred, it is necessary he should be of pure Oriental descent, it cannot for a moment be supported; as, independently of the fact, that only two mares are stated in the Stud-Book, or elsewhere, on authority, to have been imported into England, in the early days of racing, it is well known that the first British race-horses were those of British breed, changed, ameliorated, and, at last, perfected by the admixture of Eastern blood, and judicious crossing afterwards.

The effect of what is called crossing blood is as follows: The first cross gives one-half, or 50 per cent.; the second 75 per cent.; the third $87\frac{1}{2}$ per cent.; and the fourth $93\frac{3}{4}$ per cent. In sheep, after this, if the ewes have been properly selected, the difference in the wool between the original stock and the mixed breed is scarcely perceptible; but with the horse, the breeder must not stop here, if he means to produce a race-horse; and a curious fact is stated respecting sheep, on the authority of the Count Veltheim, of Brunswick, an extensive breeder of that species of stock. "It has frequently occurred to me," says he, "that rams, which, after an improvement of four or five descents, have rivalled all the *visible* qualities of the purest Merinos, when employed in propagation, have got very ordinary lambs, and consequently they are not fit to be used for breeding. On the other hand, a fact may be stated, wherein, after a very opposite cross, pure blood, with evident improvement upon the original stock, was procured on the eighth descent. The late Lord Oxford, very celebrated for his greyhounds, finding them degenerating in courage, crossed his best bitches with a bull-dog. The result was, after several recrossings with pure blood, that breed of greyhounds for which he was so eminently distinguished. The immediate descendants, however, of the Eastern horses, have almost, without an exception, proved so deficient of late years, that our breeders will no more have recourse to them, than the farmer would to the natural oat, which is little better than a weed, to produce a sample that should rival that of his neighbours, in the market."

Much speculation has also been indulged in, as to the effect of close affinity, in breeding the race-horse, or what is called breeding in-and-in; a system which has eminently succeeded in breeding cattle, and also with Lord Egremont's racing stud. Beginning with Flying Childers, several of our very best racers have been very closely bred; and it certainly appears reasonable that, as like is said to produce like, if we have high form and superior organization in an own brother and sister, that high form and superior organization would be very likely to be continued to their incestuous produce. In a work called "Observations on Breeding for the Turf," published a few years back, by Nicholas Hankey Smith, who resided a long time among the Arabs, the author gives his opinion, that colts bred in-and-in show more blood in their heads, are of better form, and fit to start with fewer sweats, than others; but when the breed is continued incestuous for three or four crosses, the animal, he thinks, degenerates. By breeding in-and-in, however, he does not insist upon the necessity of breeding from brother and sister, or putting a mare to her own sire, or the sire to her own dam; but after the first cross, to return to original blood. A recent proof of the good effect of a close affinity in race-horses may be found in the produce of the dam of his late Majesty's favourite mare Maria. By those celebrated stallions, Rubens and Soothsayer, they were worthless; but by Waterloo and Rainbow, grandsons of Sir Peter, and thus combining much of her own blood, they could run to win.

We now come to the most certain source of producing good racers, namely, the choice of stallions and mares, and the treatment of the produce in their colthood. But as regards the two first-named requisites, reference must be had to the parts of the country in which horses are intended to run. If, for the short races of Newmarket, so much the fashion of the present day, a differently formed animal would be required to one intended to clear his way on the provincial courses. But whether it be one description of a race-hosre or another, although the laws of nature are not always certain, a proper junction of shape, or similarity in formation of horse and mare, together with a due regard to blood, gives the fairest prospect of success. We admit it is difficult to account for the degrees of excellence between the running of two full brothers or sisters, where it does not arise (a common case we conceive) from some violence or impression on the womb, when the fœtus is in a soft state, or from a decline in the constitution of the mare, subsequent to her last produce; but when we find the produce of two highly-bred animals, both proved to be good, and with a proper admixture of blood, unable to race, we can attribute it to no other cause than a dissimilitude of parts in the horse and the mare, or a similitude of some parts tending to an extreme in both. Without going so far as to assert that there is no innate quality in blood, we may safely pronounce it so far from being, as some have supposed it to be, independent of form and matter, that, unless accompanied with suitable form and action, it is of very little value in a race-horse. "Sometimes," as Sancho says, "we look for one thing and find another;" but we know of no instance of a bad misshapen horse and a bad misshapen mare, however highly bred, producing good runners.

The first and most important point in the choice of a blood-mare for a racing stud, is the soundness of her constitution and limbs; although, of course, it is desirable she should be of good size and shape, with substance. How highly so ever she may be bred, and however well she may have run, if she have not a sound frame, she cannot be depended upon to breed racers. If she have never been trained, of course the risk is increased; but, in either case, her form and action must not be overlooked, as it too often is, rendering the breeding of thorough-bred stock a mere matter of chance. Should she have appeared in public, her racing capabilities are to be consulted. For example, if pace (speed) was her best, as the jockies say, a stallion should be selected, who, by the known stoutness of his running, is likely to tie her produce to pace, or, in other words, to give them both speed and endurance in a race. Her frame should be roomy, or her produce will be apt to be small, although, it must be admitted, there are exceptions to this rule. She should be of, what is termed, fashionable blood, for, if she be not, and her produce should come to the hammer, *previous to trial*, they would prove utterly worthless in the market.

It cannot admit of a doubt, that it is trespassing on the powers of nature to expect a mare, or any other female animal, to nourish her fœtus, in embryo, so perfectly during the time she is giving suck, as if she were dry or without milk. Nevertheless, it is customary to put all blood mares to the horse the ninth day after foaling, and it is almost too much to expect that the owners will let them lie fallow, although they may in some measure resemble the man who cut up his goose to get at the golden egg. During the period of gestation, however, the thorough-bred mare should be highly kept. All animals well fed, produce their species of a superior description to those which are not well fed; and nothing more forcibly shows the beneficial effect of warmth in rearing superior varieties of the horse, than that the half-starved horse of the desert should be as good as he is even now found to be.

In a racing-stud, the period of putting mares to the horse is much earlier in the year than that of any other sort, by reason of their produce being almost always called upon to go into work before they are two years old. In fact, they can scarcely be dropped too soon in the commencement of a new year, where proper accommodations are provided for them. A peep into the three volumes of the Stud-Book will satisfy inquirers into these matters, that some mares have produced more than twenty colts and fillies, and, in a few instances, the greater part of them proved good runners; but, we should be inclined to think that the average would not exceed six, as the produce of each mare. It sometimes occurs that mares are put into a breeding-stud, when affected by severe lameness in the feet. When this is the case, the operations of neurotomy or unnerving is recommended; as pain, by producing fevers, not only is injurious to the formation of the fœtus, but often causes abortion. Bad, putrid, smells, or being struck on the nose, also produce abortion in brood mares.

Virgil, in his excellent remarks on breeding horses, tells those of his readers who wished to gain a prize, to look to the dam; and, until of very late years, it was the prevailing opinion of Englishmen, that, in breeding a racer, the mare is more essential than the horse to the production of him, in his highest form, and we know it to have been the notion entertained by the late Earl of Grosvenor, the most extensive, though not perhaps the most successful, breeder of thorough-bred stock England ever saw. The truth of this supposition, however, has not been confirmed by the experience of the last half century, and much more dependence is now placed on the stallion than on the mare. The racing calendar, indeed, clearly proves the fact. Notwithstanding the prodigious number of very highly bred and equally good mares that are every year put to the horse, it is from such as are put to our very best stallions that the great winners are produced. This can in no other way be accounted for, than by such horses having the faculty of imparting to their progeny the peculiar external and internal formation absolutely essential to the first-rate race-horse; or, if the term "blood" be insisted upon, that certain innate but not preternatural virtue, peculiarly belonging to some horses but not to others, which, when it meets with no opposition from the mare, or, in the language of the stable, when "the cross nicks" by the mare admitting of a junction of good shapes, seldom fails in producing a race-horse, in his very best form. It is obvious, then, that owners of racing-studs should not hesitate at paying the difference between the price of a first-rate stallion and an inferior one; and there is always one of the former to be found, to suit every description of mare. Breeders of all kinds of horses, but of the race-horse above all others, scarcely require to be cautioned against purchasing, or breeding from, mares, or putting them to stallions, constitutionally infirm. By "constitutionally infirm," is chiefly implied having a tendency to fail in their legs and feet, during their training, which too many of our present racing-breed are given to; although the severity of training is not equal to what it was some years back. It would be invidious to particularize individual sorts; but we could name stallions and mares, from which the greatest expectations were raised, whose progeny have sacrificed thousands of their owners' money, entirely from this cause. It having been clearly shewn, not only in theory but in practice, that the diseases and defects of horses are for the most part hereditary, we may be induced to give credit to the assertion, that the Arabians, after having brought their breed of horses to the highest pitch of improvement of which they themselves considered them capable, have preserved their chief perfections, namely, great endurance of fatigue, with highly organized matter, and natural soundness of limb,—by restricting the use of stallions until approved of by a public inspector of them. Indeed, in several European states, similar precautions are taken, and stallions are provided by their governments, for the use of farmers and others who breed horses, and care is taken in the selection of them to avoid all such as have proved naturally unsound, or been affected by any disease, the influence of which may be hereditary. No part of veterinary pathology is more interesting than that which relates to the hereditableness of disease; and, as an eminent French writer (Professor Dupuy), on the veterinary art, observes, "That person will render an important service to his country, and to rural economy in general, who may show, by incontestible evidence, that those organic diseases (farcy and glanders) are very often hereditary. I knew a mare whose body on dissection presented every appearance of glanders; her filly died at the age of 4½ years of the same tuberculous affection. The other offspring of this mare inherited her particular conformation, and her propensities to bite and kick." The Professor produces three similar instances of inherited disease, all of which, he says, were too evident and well-marked to admit the possibility of any serious mistake, and were attested by the professors of the Veterinary School at Alford. Similar observations follow in relation to the diseases of oxen, cows, sheep, and swine, as also of ophthalmia in horses, all of which are transmitted from one generation to another, the effect of hereditary influence. "These considerations," continues the Professor, "to us are of the greatest moment, since we have it in our power, by coupling and crossing well-known breeds, to lessen the number of animals predisposed to these diseases. Acting up to such ideas, our line of conduct is marked out. We must banish from our establishments, designed to improve the breed, such animals as show any signs of tuberculous disease, or any analogous affection. Above all, no stallion should be allowed to remain in a wet or cold situation, in consequence of the evils likely to result therefrom."

In consideration of the preference given to the stallion over the mare, in the propagation of racing-stock, may be quoted the following passage, from Part 3d of Percival's Lectures on the Veterinary Art (London 1826). "It might be supposed that the part the male takes in fecundation is comparatively a very unimportant one; it must be remembered, however, that the copulative act is the essential first cause, that therein the action of the organs is natural and sympathetic, and that the result is the generation of a new animal, bearing a likeness to one or both of the parents; from which it would appear, although the physical part of the male is simply to project the sperm into the female, who alone has the power of rendering it efficacious, that the influence of the sperm is much greater in the generative process than we seem to have any notion of, or at least than we have been able to reveal the nature of in physiology."[1]

Rearing of Young Racing Stock.

Under all circumstances, there is too much resemblance between the speculations of the Turf and a lottery; but, as the prizes it exhibits are valuable, the most effectual means of obtaining them should be adopted. It signifies little what care and circumspection have been exercised in the selection of stallions and mares, with a view of breeding racers; the prospect of success is very limited indeed at the present day, unless the produce be reared according to the improved system acted upon in our first-rate racing establishments. Such was the pertinacity of opinion, combined with long-established prejudices, and in direct opposition to the daily acknowledged fact, of dry and warm countries having been the first to produce the horse in perfection, that it is only within a very few years that young thorough-bred stock has been reared in the manner in which it should be reared. A thorough-bred colt may now be said to be in training from the day on which he is dropped, so great is the care taken to force him into shape and substance. Not only is he drawing from the teats of his dam the milk of a highly fed animal, and consequently, in itself highly nutritious, but, before he is twelve months old, he eats nearly two bushels of oats per week. The time for expansion of frame is youth, and, when we see a two year old at the post, with eight stone four pounds on his back, which is to be seen in every meeting at Newmarket, and looking like a horse able to carry a light man after hounds, we most cordially assent to the answer given by the most experienced Newmarket trainer of the present age to the question, What is the best method of rearing a racing colt? "First observe," said he, "that the blood, or cross, is good; secondly, breed him as you would a sheep, from a roomy dam; and thirdly, give him as little green meat as possible, and as much corn as he will eat." The trainer we allude to has now retired, but he had all the young stock of the Duke of Grafton, and many of the first and most successful sportsmen in England, through his hands, and the annual disbursements of his establishment exceeded ten thousand pounds. That dry and hard food, as it is called, is the natural food of the parent stock from which our race-horses are descended, is beyond all doubt; and that the firmness of their acting parts is attributable to that, and to the warmth and dryness of the climate, is also admitted. Is it, then, to be wondered at, that breeders of horses, and not only of race-horses, have at length found out that dry food and warmth have the same effect in the Temperate as they have had, and now have, in the Torrid Zone? that they have discovered that, when colts are bred on rich succulent food, and subject to a humid atmosphere, the bulk of the body increases out of proportion to the strength of the bones; and to these predisposing causes are to be attributed most of the false points which we find in horses, such as fleshy shoulders, deficiency of muscle, weak pasterns, and flat feet? Virgil discovered this nearly two thousand years ago, and, when speaking in praise of Epirus, as suitable to the breeding of horses, emphatically observes:—

---

Race-Horse.

> "Continuo has leges æternaque fœdera *certis,*
> *Imposuit natura locis.*" *Georg.* 1, l. 60.

So careful, however, now are some of our principal and most successful breeders of race-horses to avoid these evils, that not only is a thorough-bred colt eating grass *ad libitum* become a rare sight, but he is not suffered to be exposed to rain, even in the midst of summer, no, not even to a temporary shower. The effect of rain upon horses' backs, is found to produce the worst of diseases—glanders, for instance, as is well known to all cavalry officers who have been on service with their regiments; and it cannot be innocuous to the highly-bred foal, or colt. That he should be sheltered from the cold of winter, need scarcely be insisted upon here, although we are rather inclined to think, that, in the generality of breeding establishments, he is more exposed to weather in the winter than he ought to be. There is no objection to a *moderate* allowance of carrots, and a little green food; but according to the old Greek proverb, Αλλος βιος αλλα διαιτα, *another life, another diet*, we must hear no more of the "natural food" of an animal insisted upon by many, who is so far called upon to outstrip the laws of nature as to begin to work at fourteen months old, and to appear at the starting-post at two years old, displaying the form, character, and strength of one nearly arrived at maturity. Neither is the land on which a racing-stud is situated oftentimes sufficiently considered; but a want of such consideration has been the source of great loss. It is in vain to expect success unless upon that which is dry, and consequently of sound subsoil; and what is termed "upland ground" is most favourable. Walls, independently of security, are preferable to hedges, for inclosures to breeding paddocks, as the latter harbour flies, which are very injurious to young stock, and also to their dams, in hot weather; but the present small dimensions of breeding paddocks, not exceeding a quarter of an acre, and many still less, preclude the use of hedges.

Racing colts are physicked when foals, and periodically afterwards; their hoofs, also, are pared with a drawing-knife, that, by shortening the toe, the heel may have liberty to expand. Physic, in this case, may be termed the safety valve, and such it is in reality, for this system of forcing nature cannot be free from danger. It is found, however, materially to promote growth, as indeed does the work that our racing-colts perform at such a very early age. Muscular action produces muscular strength, and growth will be the result. We have seen a colt that measured upwards of fifteen hands in height on the day twelvemonth which he had been weaned from his dam.

Racing colts can scarcely be handled too soon:—

> "Dum faciles animi juvenum, dum mobilis ætas,"

as Virgil says of the bulls; and Horace illustrates the necessity of early erudition of the human species by the excellence of horses which have been well broken in when young. The first breaking in of colts is also alluded to by Ovid, who, like Horace, is in favour of very *careful* treatment of them, and reminds us of the necessity of it in the following beautiful line:—

> "Frænaque vix patitur de grege captus equus."

The system of breaking colts, however, is not only thoroughly well understood in our racing establishments, but is accomplished with much less severity than it formerly was, and consequently with less danger to the animal.

The time of foaling is one of great interest to owners of valuable brood mares, and particularly so when the produce is engaged, perhaps heavily, or when they are of what is termed a running family. The attention of the stud-groom is directed by sundry forewarnings, the most palpable of which is what is called "waxing of the udder," and appearance of milk, which generally precede parturition two or three days, but in some instances more. As the mare brings forth on her legs, there is little fear of the foal being overlaid by the mother; but the less she is disturbed the better, lest she should trample on its legs. Her treatment afterwards is now so well understood, that nothing requires to be said about it; but a bran mash, with from four to six ounces of nitre dissolved in it, given as soon as she has brought forth, keeps off fever. The great preventive of accidents to foals, is the simple contrivance of rollers on the sides of the door-frames, which secure them from being injured as they rush out of the hovel or shed by the side of their dams, especially in cases of alarm.

Some persons prefer purchasing to breeding young racing stock, and it is difficult to determine between the advantages and disadvantages of the systems. It is true that, in the first case, the purchaser has a certainty of some return for his money, inasmuch as he gets his colt or filly, which the breeder may never get, after incurring a great expense on the mare. The price of a promising yearling, from three to five hundred guineas, is a large sum to begin with; and we cannot, in this instance, say with Varro, that "a good horse is known from the first." If purchased after he has appeared in public, at two years old, of fashionable blood, and having run in front, he is not to be purchased much under a thousand guineas, which is a large sum to realize, when added to concomitant expenses. Nothing but the immense amount of stakes for young racing-stock can justify such a speculation. For example, in 1824, a filly of the Duke of Grafton's won four thousand four hundred and fifty guineas, public money, by only starting twice.

One of the principal drawbacks from the prospects of success in a racing establishment, is a complaint called the Distemper, a sort of catarrhal fever, the cause of which is generally attributed to atmospheric influence, and also to any other which may produce what is termed a cold. Unlike common catarrhs, however, the distemper will run through a whole stud of horses; and if it do not, as it frequently does, end in an affection of the lungs, it leaves a lassitude behind it, which requires some time to remove. As a hot sun, with cold winds in spring, and the humid air of the autumn, are the chief predisposing causes of this complaint, an even temperature in the stable, and warm clothing when out of it, together with avoiding exposure to extremes of heat and cold, are the best safeguards against its attacks. It may be compared to a frost over the blossoms, which in one night blasts all former hopes of a crop.

A most interesting event to a breeder of thorough-bred stock is the trial of their racing powers, which at once decides the question of their being worth the expense of training to run, or not. There is a great deal of judgment necessary in the act of trying even old horses, but still more is required to form a just estimate of a young one, from the difficulty of knowing when he is quite up to the mark, as well as of keeping him there till it may be convenient to try him;—and it is not always so, owing to bad weather, the trial of young things being generally very early in the year. This subject, however, coming more properly under the head of Training the Race-horse, will be treated of at a future time.

But we have not yet spoken of the form of the race-horse, which we will now describe; and as nothing can be considered characteristic of a species, but what is perfect of its sort, we will so far endeavour to make the pen perform the task of the pencil, as to portray his cardinal points, as nearly perfect as such means will admit of. Nature herself, perhaps, rarely exhibits perfect models in the animal world, leaving the completion of her skill to human sagacity; neither is undeviating symmetry absolutely necessary in a race-horse. In every composite, however, beauty consists in the apt connexion of its parts with each other; and just proportions in the limbs and moving levers, coupled

Race-Horse.

with that elegance of form *in which there is no unnecessary weight to oppress the muscles*, so peculiar to the highly bred race-horse, is all that need be insisted upon in a racer. It is nevertheless hard to say what horse will make a racer; and also what will not, until put to the test; for, how many horses have appeared, which the eye of the sportsman would not wish to study, and yet have proved themselves very capital runners? This excellence, however, in those "cross-made horses," as they are termed, not misshapen ones, arises, as has been before observed, from their possessing parts conducive to speed and action, not, perhaps, very strikingly displayed, but, by means of greater length and depth, and a peculiar manner of setting on of the acting parts, enabling them to excel others, much handsomer to the eye, but wanting in either proper declivity, length, or, what is still more probable, in circular extent of those parts. Thus, as the wise man, according to the Stoics, alone is beautiful, so is a race-horse to be admired solely for those points which make him a good race-horse.

Although symmetry and proportion form a perfect figure, and they become deformities when any of the component parts exceed or fall short of their due proportions, yet it is not always necessary to measure by the standard of perfection. Suffice it, then, to state the generally approved points of the English race-horse.

We commence with the head, not merely because it has always been considered as the most honourable member in the human frame, but as it is one of the leading characteristics of the thorough-bred horse. His broad, angular forehead, gives him that beautiful expression of countenance which no other breed possesses; and the tapering of the face from the forehead to the muzzle, forms a striking contrast with the large face of the cart-horse, and the forehead scarcely wider than the face. The race-horse should have a black, lively, and rather prominent eye, which denotes a sound constitution; and as horses do not breathe through the mouth, but only through the nose, the nostrils should be rather expanded and flexible, that they may accommodate themselves to quickened respiration, as the speed of the animal increases. But they should not be over large. "Naribus *non angustis*," says Varro, and he is right. Beauty in the head of the race-horse, however, is only a secondary consideration to the manner in which it should form a junction with the neck, as on that, in a great measure, depends the goodness of his wind in a race. His jaws should not only be thin, and not approach too near together at the throat, but they should not extend too high towards the onset, or they will impede his freedom of breathing. The neck of all horses should be muscular; but what is called a loose neck in a race-horse, is not so objectionable as in a hunter, and is considered as indicative of speed. But as the head of a horse may be called the helm which guides his course, changes, and directs his motions, it is not only desirable that, as he cannot move his head, but with the muscles of his neck, those muscles should be pliant, but that he should also have what is termed a good mouth. It is asserted that the weight of the head and neck, the effect increasing with their distance from the trunk, adds to the speed of the horse, by throwing his weight forward; but this is no argument for *additional* weight or length in those parts, which ought to be duly proportioned to the trunk. The neck of the race-horse should be in no extreme, but rather long than otherwise, and not too much arched.

As horses are said to go with their shoulders, these may be considered as highly important points. They vary in form more than any other part of the horse's frame. Those of Flying Childers rose very high and fine towards the withers; whereas, a firkin of butter is said to have rested, unsupported, on the withers of Eclipse, when in covering condition. Upright shoulders, however, being an impediment to speed, obliquity of the scapula is absolutely necessary, but we do not insist upon their running fine at the withers. We consider the shoulders of Eclipse to have resembled those of the greyhound, wide at the upper part, and nearly on a line with the back. Large, or even what are called coarse shoulders, contribute greatly to strength, and are no impediment to speed, if there is proper declivity of the scapula, or shoulder-bone. The withers, when high, or thin, should enlarge gradually downwards, and there should be four or five inches between the fore-thighs, but less between the feet.

The true position of the limbs is a most material point in the race-horse, as it causes him to stand over more ground than one which is otherwise formed, although possessing a more extended frame. One of these essential points is, the setting on of, and length in, the fore-arm, or part from shoulder to knee in the fore-leg; and, another, is the declension of the haunch to the hock in the hind leg, which is termed "well let down in the thigh." It is from having those points in excess, that enables *the hare* to describe a far greater circle, and cover more ground at one stroke, than any other animal nearly double her size. In fact, the arm should be set on at the extreme point of the shoulder, which insures this act of extension, and also adds to the declivity of the shoulder. The knee should be broad and flat, and if appearing somewhat prominent, the better. All the Herod legs had prominent knees (and no legs stood work better than they did), concussion in galloping being diminished in legs so formed. The cannon, or shank, from knee to fetlock, should be of moderate length in the race-horse (longer than in the hunter), and, above all, the leg should appear flat, not round, with sinews and bones distinct; and the former appearing to be very firmly braced. The pastern of the race-horse should be long, lax, and rather small than otherwise; length and laxness serving as springs, and smallness contributing to agility, and consequently to perseverance or bottom. Some comparison will hold good between this point in a horse, and the "small of the leg," as it is called, of a man, in contradistinction to the calf. Under the pressure of fatigue, no man complains of the "*small* of his leg" giving him uneasiness, but his calves often give him notice that he has done too much. The hoof of the race-horse should be of moderate size in proportion with the leg above.

We have already alluded to the bone of the thorough-bred horse, which much exceeds that of any other variety of this animal, in its compactness and solidity; which qualities, as the span in the gallop must give a shock in proportion to its length, are admirably adapted to the race-horse. We cannot say of him, what Job said of the behemoth, that "his bones are like bars of iron;" yet, as in proportion to the muscular power of the animal, is the dense quality of the bone, that of the race-horse need not, nor should not, be large. Experience teaches us, that bones very rarely break; fractures, when they do occur in racing, being almost invariably in the joints; and rather small bone in the leg of a race-horse, supported by broad and well-braced sinews and tendons, placed distinct from the bone, and forming what is called a flat and wiry leg, is most desirable, and found to be indicative not only of speed and endurance, but likewise of soundness in severe work. It is only those who are ignorant of the anatomical structure of animals, that fix the basis of strength in the bony substances alone, not considering the muscular appendages, which constitute the main-spring of strength and action.

As the strongest bodies owe their vigour to the milk they receive in their infancy, our recommendation to keep brood mares well will not be considered as unsuitable; but the connexion between milk and bone is also deserving of a remark. When animal bones are divested of their oil and jelly, the earth which remains is chiefly lime, united with phosphoric acid. It is worthy of notice, that phosphate of lime is found in abundance in milk. This seems to indicate, that Nature thought fit to place, in the first nourishment of animals, a quantity of osseous matter, with a view to the necessary celerity of the formation and growth of the bones in the earliest stage of their lives. This is one of the numerous instances of the beneficence of the Creator, exemplified by the science of chemistry, and shews the advantages to be expected from a good flow of milk in a mare that is well fed; and it is a remarkable fact, that the nearer the female approaches to the period of parturition, the more is the milk charged with this calcareous phosphate. Nor is it until the digestive organs of the foot are sufficiently strengthened, to answer the purposes and work of animalization, that this earthy salt disappears.

But to proceed with the form of a race-horse. The race-horse should have length, but the length should be in his shoulders and in the *quarters;* that is, the part posterior to the hips, and not in his back. To give him that elegance of form for which he is so conspicuous, there should be no acute angle or any straight line. His shoulders should go into his neck at the points, *unperceived,* and his back should sink *a little* behind the withers, which gives his rider a good seat, and does not in the least diminish his strength. On the contrary, horses with very straight backs are generally deficient in their fore-quarters, as well as in their action; and we have known some very good racers even what is termed hollow-backed. There should be a little rise in the loins, just behind the saddle; but the race-horse should not be too closely ribbed up. The ribs should stand out from the spine, producing what is called a round barrel, together with depth of carcass, a formation which not only gives strength of body and constitution, but, by admitting the intestines to be comfortably lodged within the ribs, imparts freedom of breathing, activity and beauty to the whole frame of the horse, other parts being proportional. These useful points, however, must not be carried to an extreme, or the horse may be what is termed "too heavy for his legs;" and we know that light-bodied horses save their legs much in their gallops, which accounts for mares and geldings standing the severity of training to a later period of life than stallions, by reason of the former requiring less work, from not generally carrying so much flesh as the latter.

There is no part, excepting the head, so truly characteristic of high breeding in the horse, as his haunch. If a little of the elegance of the parts, however, is diminished by the width of the hips, it will be recompensed by increased strength in the animal, as is the case with broad-shouldered men; and when accompanied with good loins, these protuberances of the ilium can scarcely be too great for the purposes of power and action. We next come to the thigh, the form and substance of which is most material to the race-horse; for although horses are said to go with their shoulders, the power to give the impetus in progressive motion comes from behind. With all animals endowed with, and requiring extreme rapidity of, motion, the thigh is furnished with extraordinary powers and length: the hare, for example, whose thighs are let down to a great extent for their size, and the lower part of the hinder leg placed under them, as that of the racer should be, from a proper curve of the hock. The speed of the ostrich arises from the power of the muscles from the pelvis to the foot; and the thigh of the fighting cock is a point much considered by breeders. It is not necessary that a race-horse's thigh should be very large, but it should exhibit well developed muscle. Descending lower in the limb, we arrive at the hock, a very complicated joint, but the form of which is most important in the race-horse. It should be large and lean, and the point of it projecting behind the body, which greatly increases the power of the lever in action, as will presently be most satisfactorily shewn.

Race-Horse.

Size.

The point of perfection in most things lies at a middle distance between two extremes, and such is the case here. The medium height, about fifteen hands two inches, four inches to a hand, is the best for a race-horse. As the long beam breaks by its own weight, so large animals have rarely strength in proportion to their size. In fact, if there were any land animals larger than those we know, they would hardly be able to move at all. On the English Turf, however, the very large horses that have appeared at various periods of its existence, have, with a very few exceptions, not been found so good under high weights, as those of a medium height; and several instances are on record (Meteora, Whalebone, and others, for example) of the best horse of his year being very nearly the lowest.

The following are amongst the principal and essential points of a race-horse, pointed out by Mr Darvill in the second volume of his "Treatise on the Care, Treatment, and Training of the English Race-horse," London, 1834.

"His head should be small and lean; his ears small and picked; his eyes brilliantly large; his forehead broad and flat. . . . . . His throat should be clean, and fine from the butt of the ear down to its centre, with a good wide space between the jaw-bones, which latter should be thin. . . . The neck should be moderate in length. I prefer its being wide; I mean its width should be formed by the substance of muscles which pass along each side of the top part of it; from the withers to the head it may gradually rise a little in its centre, but by no means to any extreme, as I have a great aversion to a high-crested race-horse. Indeed, I would prefer that his neck should be as I have described his face, rather of the ewe or deer-like shape, than that it should be loaded on top, which I will by-and-by explain. As to the lower part of the neck, I have no very particular remarks to make, further than the trachea or windpipe should be spacious and loosely attached to the neck on its way to the lungs.

"The withers may be moderately high, and, if the reader like, they may also be moderately thin; but, with respect to this latter point, I am not so very particular, provided the shoulders lay well back. From the withers the back commences. I confess, that appearance may be in favour of a horse that has his back a little low or hollow. As a saddle-horse this may be all very well, but for a race-horse, to have strength and liberty of stride, his back should be straight and moderately long, with the shoulders and loins running well in at each end. The loins should have great breadth and muscular substance, so much so as for them to have the appearance of being raised as it were on their surface; and those muscles posterior to the loins should fill up level the top part of the quarters to the setting on of the tail, which latter should be set on pretty high up."

After describing the fundament, which, if small, close, and tight, and rather projecting than otherwise, Mr Darvill considers as a good constitutional point, he thus proceeds:—"I now come to speak of the body, or what is by some people commonly called the 'middle piece' of the horse, and which is divided, internally, into two cavities by a muscular substance called the 'diaphragm.' The anterior cavity, the chest, contains the lungs, the heart, &c. The posterior one, the abdomen, contains the stomach, intestines, liver, kidneys, &c. Now, with respect to the external form of the body, which contains and protects all those numerous organs so important to life, I shall first make my observations on the chest. To use a common phrase, and somewhat an expressive one, a horse in this part should be what is called 'well over the heart,' that is, he should be deep in his girth, round or well arched in his ribs. I mean by this, that a rider on the back of a race-horse (as they are generally better about the chest than horses in common use), should feel he has some breadth or substance between his legs; and there should be a good swell of muscle before his knees, or the centre of the flaps of the saddle. The chest, thus spaciously formed, gives room for respiration, so that, in training, the horse's wind can be brought to the greatest perfection, which enables him to run on in long lengths. The next part to be treated of is the abdomen or belly, or what is usually called the carcass. It may perhaps appear a little strange, but I have a great aversion to what is commonly called a good carcassed horse, nor am I particularly partial to a large sheathed one. I like both these parts to be in the medium, as I do also that of his being well ribbed up. It is true that a horse being well ribbed up denotes strength, and a short close made race-horse is, in running, handy at his turns, and, as I have already noticed, he is generally a pretty good one under high weights over a small round cock-pit course; but this description of course and sort of running is not now so much practised as formerly, or rather it is a sort of racing that does not exactly suit long-striding horses, as most of those are that run in Newmarket. Another thing is, that horses with large carcasses are mostly great gluttons; they put up flesh very rapidly, and are very difficult and troublesome to train, in consequence of their constitutions being too strong, or proportionably too much for their feet and legs. Such horses not only seldom remain long in training, but they cannot remain long in condition without their becoming stale in themselves, as also on their legs, and those are my reasons for objecting to very large carcassed horses; yet I do not wish horses to be what is termed 'tucked up' or waspish in their carcasses. I like a horse's carcass to be in the medium; that is, it should be straight and handsome from behind the girths of his saddle; and what will make up sufficiently well, and give him sufficient strength of constitution, is the well formation of the parts already noticed, as the chest, the loins, and the fundament.

"To return to the fore-extremities. The shoulders commence from a little below the withers; they should lie most particularly well back, should be deep, broad, and muscularly strong; yet those muscular parts should appear to the eye as being moderately so, that is, not unproportionally loaded: These muscles should be distinctly seen, there should be no appearance of fat, or, as it is technically termed, 'adipose membrane.' The shoulders cannot well be too oblique in their descent to the front of the chest; here, on each side, a joint is formed by the lower part of the scapula or shoulder-blade being united with the upper part of the humerus or arm-bone. Those joints, thus formed, are usually called the points of the shoulders, which points should appear straight or level. There should be no coarse, projecting, or heavy, appearance about the points of the shoulders of such horses as are intended to race; nor indeed does this often occur, unless where it happens that the chest or counter of the horse is unproportionally wide. In taking a front view of the chest, it should appear moderate as to breadth; and if its prominency is at all to the extreme, it should be in consequence of the fulness or substance of those muscles covering the breast, which muscles should be lengthy, and their divisions distinctly to be observed. The fore-arm should be broad and long, and most particularly well furnished with muscles on its top parts, inside as well as out; I mean by this, that the muscles on the top and inside of the arm should here be so large as to leave but a moderate space between the fore-legs, immediately under the chest, and which muscles should appear, as those in front of the chest, distinctly divided. The posterior part of the top of the arm is called the 'elbow,' this should appear (the horse in condition) somewhat on a level with the body; if it at all deviates from this appearance, I would prefer its standing in, to that of its standing unproportionally out. The knee-joint should be large, broad, and flat in front; generally speaking, the larger and broader all joints are in reason the better and stronger they are; and the longer, coarser, and rougher, their projecting points or *processes* are, the greater and more secure will be the lever for the muscles or tendons to act upon, provided such projecting parts or joints (as the hocks and pasterns) do not amount to disease, as that of producing spavins and ring bones. The legs from the knee to the fetlock, cannot well be too short, neither can they well be too broad or too flat, nor their flexor tendon scarcely be too large or appearing too distinctly divided, as it were, from the leg. The fetlock-joint should also be large, and the pastern proportionally strong, but its length and obliquity should be in the medium. The wall or crust of the feet should also be moderately oblique, with the heels open, and frogs sound; this, indeed, is generally the state of racing-colts on first bearing their paddocks, if their feet have been paid proper attention to during the time they may have remained there. Yet, the feet of such of them as have been some time in work will occasionally get out of order; they grow upright and strong; the horn gets hard and brittle, and the heels more or less contracted, almost all of which defects are too often occasioned from the want of proper attention being paid to them at the time of shoeing, and of proper applications being applied to them in the stables. With regard to the structure of such horses feet, and the diseases of them, as also the method of shoeing and plating them, a description will be found in the different chapters on those subjects in the first volume. Previous to concluding my remarks on the fore extremities, it may not be amiss to observe to the reader, that, supposing him to stand opposite to those parts of the horse, if the animal is formed in them, as I have already described the centre of the top part of the fore-arm, to be well placed, ought to be nearly or quite in a parallel line with the top or fore-part of the horse's withers; and again, from the top part of the fore-arm down to the foot, for the horse to stand firm and well, and have the power of using his fore-legs well, he should stand perfectly straight on them; I mean by this, they are not to appear too much under him, or too much out or away from him. Suppose again, for example, a man standing in front of the horse, and here taking a view of the foot, the centre part of the wall or crust should be in or on a parallel line with that lower part or joint of the shoulder, commonly termed its point. A horse's feet, thus placed, will neither be too much out or too much in; but should his feet deviate from what I have here observed, by amounting to a fault, in turning too much out or too much in, I should prefer their being a little out, to that of the other extreme of turning in, and being what is called 'pigeon-toed.'

"I shall now proceed to describe the hind-quarters or posterior extremities. As may be supposed, the well formation of those parts is of the utmost importance to a race-horse in his running; it is, therefore, necessary that they should be, in breadth, substance, and length, of very superior dimensions. The hips should have a great breadth between them; and if they are a little coarse or projecting so much the better, provided such coarse projections are not in the extreme, or appear vulgar or unsightly. From the centre and posterior part of the loins to the top of the tail is called the 'croup,' and should be of great length; and, if it deviates from that of a straight line, it may be somewhat arched in the centre; the croup being thus formed gives great breadth to the top of the quarters, the length of which, from the croup down to the hock, cannot scarcely be of too great an extent, in order that there may be sufficient room here for the attachment of those broad, powerful, lengthy, and distinctly divided muscles on the outside of the quarters and thighs; and there should also be a similar portion of such muscles on the inside of the

Race-Horse.

quarters and thighs; so that a man, who is a good judge, taking a posterior view, may observe how the horse is made. In this position he should be, as it were, struck by the appearance of the great breadth and length of the back part of the quarters, and as he moves his head to the right or left, the centre and outside of the quarters and thighs, and the swell of the muscles, should appear beyond a level with the hips. The upper part of the muscles on the inside of the quarters should appear quite close to each other, so that no vacant space should be visible between them, as that of an appearance of the horse being (if I may thus express myself) chucked up in the fork. Such should be the lengthy and muscular quarters of a well made race-horse.

"The stifle-joint should be in a direct line under the hip, and the length from this joint to that of the hock cannot reasonably be too long, and the farther out of the angular or oblique position of the thigh-bone the better, so as to admit of the back part or projecting point of the hock appearing some distance out beyond the top of the hind quarters; those parts being thus formed, admit of a very considerable lever for the main tendon here to act upon the tendon Achilles, which, like the flexor one of the leg, can scarcely be too large or too distinctly seen in its commencement, from the lower part of the quarter to its insertion into the posterior or projecting point of the hock, the os calcis. The hock should be broad and wide, with a clean lean appearance, and those soft parts which are occasionally the seat of through-pins and bog spavins, in a sound well formed hock, should appear more as cavities than as having the above-mentioned projections, and which are sometimes the cause of lameness. The hind-leg, like the fore one, should be short, broad, flat, and straight; the trifling angle formed by the hock should, together with the moderate obliquity of the pastern, bring the extremity of the toe nearly under the stifle-joint."

Action of the Race-Horse.

As amongst the Egyptians, the lion was the hieroglyphic of strength, so was the horse of agility; and truly nothing displays it more elegantly than he does, when gamboling in a state of liberty. In the race-horse, action, as in eloquence, is the next thing to substance; and *virtus in actione*, should be the horse-breeder's motto. But the action of the race-horse is of a nature peculiar to his calling. He must not only possess great stride in his gallop, the result of great proportion in his limbs and moving levers, but also a quickness in repeating that stride, or he would lose in time what he gains in space. It is then when stride and quickness are united, that the fleet racer is produced; and in his race with Diamond, Hambletonian is asserted to have covered twenty-one feet at a stroke at the finish of it; and Eclipse is generally believed to have covered eighty-three and a half feet of ground in a second, when going at the top of his speed, which, by a calculation by Monsieur Saintbel, amounted to about twenty-five feet of ground covered at a stroke.

The action most approved of in a racer, as describing the greatest extent, with the least fatigue to the animal, is what is termed on the Turf "round action;" that is, when, on a side view being taken of a horse in his gallop, his fore legs appear to form a wheel or circle. Different ground, however, requires different action; and the large, long striding horse may be beaten on a hilly, or turning course, by one of a smaller size, but with a shorter stride, which prevents the Newmarket courses being a certain criterion of a good runner at Epsom, which is very trying ground. The state of the ground, likewise, whether wet or dry, soft or hard tells so much in a race, as often to give it to a horse very little thought of at starting, as was the case with Tarrare, winner of the St Leger, at Doncaster, in 1826. The celebrated Euphrates, the winner of so many gold cups, and who ran till he was in his teens, was nearly a stone below his usual form, after even a hard shower of rain. This variation of fleetness corroborates our assertion, that the virtue of what is termed blood is mechanical, or, what is the same thing, that the excellence of all horses is mechanical, and that the smallest deviation from a true formation of the acting parts operates so powerfully as to render them, under certain exertions, nearly valueless.

Wind.

It is true, "speed wins the race;" but to make it available to the race-horse, it must be accompanied by endurance, or "bottom." A great promoter of this is clear wind, or freedom of respiration, the want of which makes the war-horse rebel in the manège, the hunter run into his fences, the draught-horse fall, as if he were shot, and the racer either stop, or bolt out of the course. In fact, when the organs of respiration are fatigued, all animals are nearly powerless. The cause of good wind may be distinguishable to the eye, and arises chiefly from depth in the fore-quarters, which implies a capacious thorax or chest. However wide a horse may be in his foreparts, he will not be good-winded unless he is, at the same time, deep. But still wind in the race-horse depends on something more, on the nature of his constituent and component parts, which, if in proper proportion, impart to him strength and agility, giving him that easy action which will not readily fatigue these organs of respiration; and so enable him to run on, when others, less gifted by nature than himself, are forced to slacken pace. The good effect of clear wind in a race-horse is in fact twofold; first, It gives him signal advantage in a race; and, secondly, Horses thus organized require less work to make them fit to start.

The following passage on this point is worthy of remark: "When the animal powerfully exerts himself, a more ample supply of pure blood is required to sustain the energies of life, and the action of the muscles forces the blood more rapidly through the veins; hence the quick and deep breathing of a horse at speed; hence the necessity of a capacious chest, in order to yield an adequate supply, and the connexion of this capacity of the chest with the speed and the endurance of the horse; hence the wonderful relief which the mere loosening of the girths affords to a horse blown and distressed, enabling the chest to expand, and to contract to a greater extent, in order to yield more purified blood; and hence the relief afforded by even a short period of rest, during which this expenditure is not required, and the almost exhausted energies of these organs have time to recover. Hence, likewise, appears the necessity of an ample chest for the accumulation of much flesh and fat; for, if a considerable portion of the blood be employed in the growth of the animal, and it be thus rapidly changed, there must be provision for its rapid purification; and that can only be effected by the increased bulk of the lungs, and the corresponding largeness of the chest to contain them."[1]

Certain thorough-bred horses would deceive an inexperienced observer as to the real state of their organs of respiration, by an appearance of difficulty of breathing, which, in reality, they do not possess. The term for this apparent defect is, in one instance, hard breathing, or high-blowing, and in another "cracking the nostrils." Of the first description was the celebrated Eclipse, whose breathing in

---

Race-Horse.

his gallop could be heard at a considerable distance; and of the latter (still more common) may be reckoned many of the best racers of past and present days. Indeed, a race-horse cracking his nostrils in his exercise, and snorting well afterwards, are considered indicative of good-windedness. On the other hand, when a race-horse becomes a roarer, which is a common effect of a severe attack of the epizootie, called the Distemper, he is rarely able to struggle in a race, although there have been several instances of winners under such very unfavourable circumstances.

Temper is a property of much importance to the race-horse, subject as he is to its influence under more trying circumstances than most other descriptions of horses. In the first place, his fine and nearly hairless skin, softened and cleansed as it is by frequent copious perspiration, is so highly sensible to the friction of the wisp and brush, as to induce him to try to rid himself of his tormentor, by attacking the person who is dressing him, and thus becomes vicious in the stable. It will also be recollected that he is at this time, perhaps, in the very highest state of condition and good keep of which his nature is susceptible. On the race-course, again, he has often to encounter the (to him) unnatural sound of music, and many strange objects; perhaps two or three false starts before he gets into a race; and too often, when doing his best in a race, very severe punishment both by whip and spur. It is in his race, however, and chiefly in the last struggle for it, that the temper of the race-horse is most put to the test; and, if really bad, he either runs out of the course, to the great danger of his rider, and to the inevitable loss of his owner and those who have betted on his winning, or he "shuts himself up," as the term is, and will not head his horses, although in his power to do so. It is evident, then, that breeders should not send mares to stallions of known bad temper, as nearly all those propensities are found to be hereditary; and we could name one or two of the best horses of the present day, who are generally rejected as stallions to breed racers from, by reason of these propensities.

It would be absurd to draw a comparison between the English race-horse in training, and the horse of the Desert, "educated," as Mr Gibbon eloquently says of him, "in the tents, among the children of the Arabs, with a tender familiarity, which trains him in the habits of gentleness and attachment." Nevertheless, we are inclined to believe that the tempers of many naturally quiet horses are made uncertain, and oftentimes decidedly vicious, by want of proper judgment, as well as good temper, in those also who have the management of them. Brutes, like men, demand a peculiar mode of treatment, when we require them to do their utmost for us; and it is certain that this principle holds good in regard to both, namely, *that, in general, kindness gains its point, cruelty provokes resistance, and a proper degree of severity produces obedience.* The panther in the fable knew who fed her with bread, and who pelted her with stones; and we may be assured, that so noble and high-spirited an animal as the horse feels with acuteness sensations of pleasure and pain.

We often hear it asserted that the British thorough-bred horse has degenerated within the last few years, and is no longer the stout and long-enduring animal that he was in the bygone century, particularly during the last twenty years of it. We are inclined to believe that there is some truth in this. We do not think we have such good four-mile horses, as they are termed, as formerly, which we consider easily accounted for. They are not wanted, very few four-mile races being now run, even at Newmarket or in the country, and, therefore, a different kind of race-horse is sought for. It may, however, be true, that the inducement to train colts and fillies, at a very early period of their lives, for these short races, has had an injurious effect on their stamina, and, consequently, on the stock bred from them. Formerly a horse was wanted for a lifetime, now he is cut up in his youth to answer the purposes of perhaps but one day;—a system, we admit, quite at variance with the original object of horse-racing, which was intended to benefit the community, by being the means of producing, as well as displaying, the constitutional strength of the horse in its very highest perfection. Another cause may have operated in rendering thorough-bred horses less powerful than they were, or less capable of enduring severe fatigue. During the period of high weights and long courses, horses and mares were kept on in training until after they had arrived at the age of maturity, neither did they begin to work so soon; whereas now, no sooner have they won, or run well for some of our great three year-old stakes, than they are put into the stud to produce racing stock, which is perhaps to be used much in the same manner as they themselves have been used, or, we should have rather said, abused.

But, admitting this alleged falling off in the powers and performances of the British thorough-bred horse, it may be the result of causes unconnected with those already noticed. Although there may be no era of greater intellectual brightness than another in the history of any animal but man, yet, as is signified by Plato in the eighth book of his Republic, there have always been periods of fertility and sterility of men, animals, and plants; and that, in fertile periods, mankind, as well as animals, will not only be both more numerous, but superior in bodily endowments, to those of a barren period. This theory is supported by the relations of ancient historians, in the accounts they give of animals which no where exist at present, and in the properties they ascribe to some of those which now do exist.

But to return to the alleged alteration for the worse in the British race-horse. We admit the fact, that he is not so good at high weight over the Beacon at Newmarket, or any other four-mile course, as his predecessors were, whose descent was closer than his is to the blood of Herod and Eclipse, and the descendants of that cross, said to be the stoutest of any. Nevertheless he is, in his present form, more generally adapted to the purposes to which the horse is applied. He has a shorter, but more active, stroke in his gallop than his predecessors had, which is more available to him in the short races of the present time than the deep rate of the four-milers of old times; and as he is now required to start quickly, and to be on his legs, as the term is, in a few hundred yards, he is altogether a more lively active animal than formerly; and, as such, a useful animal for more ends than one. In former days, not one trained thorough-bred horse in fifty made a hunter. Indeed few sportsmen had the courage to try the experiment of making him one. He went more upon his shoulders, as well as with a straighter knee, than the modern race-horse does, and required much greater exertion in the rider to pull him together in his gallop. All those sportsmen, however, who remember such horses as the late Earl Grosvenor's, John Bull, and Alexander, must admit, that, in form and substance, they were equal to carrying the heaviest weight across a country, and the last mentioned horse was the sire of several very powerful, at the same time very brilliant hunters. But as it is action after all that carries weight, the thorough-bred horses of this day are not deficient in that respect, unless undersized; and there are more thorough-bred hunters at this period, and have been more for the last thirty years, than were ever known before. This improvement in action also qualifies the full-bred horse for the road, whereas formerly not one in a hundred was fit to ride off turf. Indeed daisy-cutters and thorough-bred horses were nearly synonymous terms; but at present a young lady on a bit of blood is an every day sight; and a young gentleman on any thing else in the parks, or on his road to hounds, is become rather a rare one. This is a very saving clause to breeders of race-horses, as a market is now generally found for such as are undersized, or tried to be deficient in speed for racing; whereas in former days, a bad race-horse was, like Rosinante, neither saleable nor pawnable.

Speed of the Race-Horse.

All animals in a state of domestication exhibit powers far beyond those that are natural to them in their wild state, and writers on the horse have advanced to the utmost verge of possibility, in recording the maximum speed of the English race-horse. Most of the instances stated by them, such as Flying Childers having run a mile in a minute, are unsupported by authority, and therefore not worthy of regard. That the horse, however, has ever been considered the swiftest beast of the forest, may be gathered from the frequent allusions to his fleetness by inspired as well as by heathen writers. Thus, the chariot-horses of Oenomaus, King of Elis, were said to be begotten by the winds, emblematical of their prodigious swiftness; and Homer represents the steeds of Achilles to be the produce of Zephyrus (the west wind, said to be the swiftest of any), and Podarge, whose name signifies speed. Nor is Virgil far behind the rest in his encomium on the fleetness of his colt, which he makes to challenge the very whirlwind itself. As it is speed, however, that wins the race, it is most essential to the race-horse, provided it be accompanied by stoutness; and unless we wish to fly through the air like Pacolet on his wooden horse, we may be contented with the speed of the present English race-horse. Perhaps the following is a fair specimen, and, as it is of so late a date, the same uncertainty does not attach to it that hangs over the unsupported traditions of our earlier racing days. In 1832, Theodore, the property of the Honourable Edward Petre, and winner of the Doncaster St Leger stakes, ran the distance, being one mile six furlongs and one hundred and thirty-two yards, in three minutes and twenty-three seconds, carrying 8 stone 6 lb. He was trained and tamed by the late Mr Croft, who also trained the second and third horses in the same race.

Expenses of a Breeding Racing-Stud.

Some persons must be breeders of race-horses, but whether to profit or loss, depends on various circumstances. Amongst them may be reckoned the following:—Judgment in selecting the parent stock or blood; conveniences for keeping the produce well and warm, and on land suitable to breeding; and plenty of money at command, to enable a breeder to purchase mares of the very best racing families, and to put them to the best of stallions. When this is the case, we think breeding (we mean quite distinct from risk in racing) would seldom fail to pay, if the foals were sold off at weaning time, or even at a year old. A few years back, eight of the Earl of Durham's *foals* realized L. 200 a-piece; and, still later, several of Mr Nowell's (of Underley Hall, Westmoreland) yearlings fetched the enormous sum of L. 500. No doubt, in all studs, great loss is sustained by a certain proportion of the young stock which promise to be small and not worth training; but here breeders are often deceived. For example, the late Lord Grosvenor sent Meteora, the best mare in England of her day, to Chester Fair, when two years old, to be sold for L. 16, because she was considered as too small; and he also suffered Violante, the best four-mile racer of her day, to be sold, *untried*, for L. 50, but fortunately purchased her again. The great prices, however, occasionally paid to breeders for some horses (4000 guineas, for example, to the Earl of Jersey for Mameluke, and 3000 guineas a-piece have lately been given for other three year-old colts) make up for the loss inseparable from such as, by misshape, diminutive size, and casualties, are culled out, and sold for what they will fetch, which seldom amounts to much.

Value of Stakes and Prizes.

Agamemnon is made to say, that that man would be rich who had treasures equal to the value of the prizes the horses had won, which he offers to Achilles. We are inclined to think, that if this king of Argos could come amongst us now, he would find prizes more valuable than any contended for in his time; and that sterling cash, and not "the bubble honour," is the main object of the British sportsman on the Turf. But here is the inducement to the great expenses of a racing breeding-stud: It is possible that a three-year-old *colt* might win, at three starts, the enormous sum of 8350 guineas; and a three-year-old *filly* might win the still greater amount of L. 11,100.[1]

Colour of the Thorough-bred Horse.

The beauty of forms observable in the animal system is subordinate to their general utility, and they please us in proportion to their aptitude to unite these two objects. We admire the elegant make of a swan, but the pleasure is doubled when we behold the ease and dignity of its motion. The colours, however, which Nature has bestowed with such profusion upon the surface of some of these animals, birds in particular, exhibit beauties independent of aptitude, and could only have been intended for their adornment. The prevailing colour of the thorough-bred horse is peculiarly elegant and chaste, being a bright bay, with black mane and tail, and black legs to correspond, although occasionally relieved with a small white star on the forehead, or a white heel of the leg. It is remarkable, that what may be termed vulgar colours, such as light sorrel, or dun, or brown with mealy muzzle, are very seldom met with in the thorough-bred horse; and we know but one instance of the pie-bald, and very few roans.[2] Black is not common, nor approved of, although several of our best racers, almost all the Trumpator blood, have been of that colour. The real chestnut prevails a good deal, and is quite equal to the bay in the richness and brightness of its hues. Such was the colour of Eclipse, and, as is the case with game-fowls, in the breeding of which there are instances of a reversion to the original colour, after fifteen descents, it is not uncommon for thorough-bred stock to be chestnuts, although got by a bay stallion out of a bay mare, or from sire and dam of any other colour, provided the blood runs back to his, Eclipse's, source. Indeed, a small dark spot which that celebrated horse had on his quarter, has been frequently found in his descendants in the fifth or sixth generation.

It is an old and trite saying, that "a good horse cannot be of a bad colour;" nevertheless, colours of horses are, to a certain extent, indices of their physical powers. Such has proved to be the case with men; and it was found in the ill-fated Russian campaign, that men of dark complexions and black hair bore the severity of the climate better than men of an opposite appearance to them. It is, however, rather a remarkable fact, that by far the greater number of eminent English prize-fighters have been men of light, not dark, complexion. The ancients reckoned thirteen colours of horses, giving the preference to bay (badices).

---

[1] *Vide Racing Calendar*, 1834, for amount of the twentieth Riddlesworth stakes, at Newmarket; the Derby and Oaks, at Epsom; and the St Leger stakes, at Doncaster.

Race-Horse.

A second-rate description of racer has lately been very prevalent in England, Newmarket excepted, known by the term "cock-tail," or *half-bred* horse, as he is called, but improperly so termed, because the stain in him is generally very slight indeed, and too often difficult to be traced. Many objections are raised by sportsmen, who are thorough racing men, and who wish well to the Turf, against the cock-tail racer, and for very good reasons. In the first place, if really half-bred, he resembles the royal stamp upon base metal, for no half-bred horse is deserving the name of racer, nor will he stand the necessary preparation. Secondly, what are called half-bred stakes, some of which are very good, have been the cause of a great many frauds being committed, by bringing horses to run for them under false pedigrees, which will ever be the case, from the great difficulty of proving a horse to be thorough-bred, whose dam may have been purchased by accident, or in some clandestine way, and still perhaps of pure racing blood. Again, as there is no scale by which the degree of impure blood, which qualifies a horse for those stakes, can be measured, the breeder of the cock-tail, of course, avails himself of the parent stock in which the slightest possible stain can be shewn, which indeed has been attempted to be shewn in some of the best race-horses of later times. In this case, an animal is produced against which no half-bred horse, in the proper acceptation of the term, has a chance, and he sweeps the country of all the good stakes; and some such horses, (Habberley, for example) have proved themselves superior to many of the thorough-bred racers of their year. But the breeding of horses for these stakes is any thing but beneficial to the country, the great object of racing. It encourages a spurious race of animals, often possessing the faults of the blood horse without the strength and activity of the hunter, and it was for the latter description of horse that this stake was first intended. *Bona fide* hunters' stakes would be advantageous, if *open to all horses* bringing certificates of their having been regularly hunted throughout a season, but not merely ridden by a boy to see a fox found; and giving no allowance to the horse called "half-bred." Let the best hunter win, which would encourage the breeding of strong thorough-bred horses, which make the best hunters of any;—a fact no one who has ridden many of them will deny.

Weatherby's General Stud Book.

To assist in the detection of spurious blood, and the correction of inaccurate pedigrees, is the chief purpose of this excellent publication, now increased to a third volume, and forming a part of every sportsman's library. Some attempts have been made by Mr John Laurence, a voluminous, but by no means a correct, writer on the Horse, to disturb the pedigrees of several of the first stallions of their time, and from which several of the distinguished racers of the present day are descended; and all upon hearsay evidence, without being able to substantiate one single fact in proof of his vague assertions. He has doubted the pedigree of Eclipse, put the blood of Sampson into Highflyer, where it never existed, and has thought proper to pronounce Sampson to have been a low-bred horse, on the authority of some old Yorkshireman he picked up on the road, although in his last work on the Horse he admits him to have been one of "the truest four-mile horses that our Turf has produced; was but once beaten, and also proved a capital stallion, as sire of Bay Mollon, Engineer," &c. Such matters as this would be scarcely worthy of notice, were it not with a view of cautioning the public, foreigners in particular, from being led into errors respecting the purity of our racing blood. Sampson was an animal of immense power, so were John Bull and Alexander; he might have had coarse points, so have the stock of Partisan and Blacklock, two of the best stallions of the present day; but who would deny their purity of blood on that account? Mr Laurence has been often called to account for these and similar misstatements, but he is inaccessible to correction. *Sic accepi*, Anglice, "As I have heard," is the main foundation of many of his assertions; and he claims the woman's privilege of having the last word.

THE HUNTER.

There is no description of horse which could be applied to so many purposes, racing excepted, as the powerful English Hunter. Setting aside his own peculiar services in the field, he is fit to carry a man on the road, in the field of battle, and he answers for every kind of draught. Indeed, we are inclined to believe no horse would equal him in ploughing; and as for road-work on harness, either slow or fast, nothing could touch him, in a carriage properly suited to his powers. It is, however, no less true than singular, that out of a hundred sportsmen assembled at the meeting of a pack of fox-hounds, not half-a-dozen would be found mounted on horses which they themselves had bred. This arises from two causes: First, the greater part of them have not patience to await the arrival of a young horse at his best, and consequently sell the few they do breed, without giving them a fair trial; and, secondly, such has, of late years, been the prejudice against riding mares in the hunting field, that they have been chiefly left in the hands of farmers and yeomen, who are become the principal breeders of English hunters. Neither do hunters find their road direct from the breeder to the studs of noblemen or gentlemen. They generally go through the hands of an inferior country dealer, from whom they are bought by the principal London and country dealers, and sold by them to the sportsmen of the various hunts. There are, of course, exceptions to this proceeding. A great proportion of English yeomen and farmers are very excellent horsemen, and, as such, having the capability of making their young horses into hunters, and, distinguishing them by riding them afterwards with hounds, obtain now and then as high a price for them as they fetch after having passed through the hands we have described. It is, however, to be lamented that the last-mentioned description of persons, the breeders and trainers of young hunters, do not, for the most part, realize such large prices as the first, although fully entitled to it, as a reward for their trouble and skill.

It is impossible to lay down any precise rules for breeding hunters, so many collateral circumstances being necessary to be taken into consideration. For example, Pennant, in his Zoology, says, "Our race-horses are descended from Arabian stallions, and the genealogy faintly extends to the hunter." From this we learn the interesting fact, that a wonderful change, within the last sixty or seventy years, has taken place in the form and character of this sort of horse, inasmuch as, in the opinion of some of the first of our English sportsmen, and such as put the powers of the horse to the most severe test, the hunter of the present day is not in his perfect form unless quite thorough-bred. This part of the subject we shall discuss hereafter; but as there are several of our hunting counties not at all suited to this description of horse, the thorough-bred hunter, and a large portion of our sportsmen who, some by reason of their weight, and others from prejudice against them, neither can nor will ride them, we may safely assert, that not more than a twentieth part of English hunters are at this time of quite pure blood. We will, however, set forth what we consider the best properties of the full-bred and the half-bred hunter, as he is called, as also the most probable means of breeding each kind to advantage; at the same time venturing an opinion, that, when their individual capabilities are put into the scale of excellence, the balance will incline to the former.

One great obstacle to the general success in breeding hunters is, not so much the difficulty of access to good stallions, but of making breeders believe that it would be their interest to send their mares to such as are good, although at an extra expense. Most rural districts, in other respects favourable to horse-breeding, swarm with covering stallions, the greater part of which have proved very bad racers; but which, falling into the hands of persons who are popular characters in their neighbourhood, and covering at a low price, get most of the farmers' brood mares sent to them, their owners never reflecting, as they gaze upon these misshapen animals, that Nature will not go out of her course to oblige them, but that, in the animal creation, "like begets like." Neither does the evil stop here. So much is this made a matter of chance instead of one of judgment, should the produce of a mare sent to one of these bad stallions be a filly foal, and she proves so defective in shape and action as to be unsaleable at a remunerating price, she remains the property of her breeder, and in time becomes herself a brood-mare. What, then, can be expected from such produce? Why, unless chance steps in and supplies the defect of judgment, in the first instance, admitting that she is sent to a better stallion than her sire was, by the procreative powers of the male so far exceeding those of the female, as to produce a foal free from the defects of the dam, another shapeless, unprofitable animal is produced. Nevertheless, in the course of time, perhaps this produce, if a female, however bad she may prove, is also bred from, and thus a succession of shapeless horses is produced, to the certain loss of the breeder, and much to the injury of the community. Under the most favourable circumstances, and with the aid of good judgment, we cannot consider horse-breeding to be a certain source of gain: yet there are many inducements to try it as one branch of rural economics. The money goes out a little at a time, or by degrees, and therefore it is suitable to such occupiers of land as cannot embark in more extensive speculations, and it returns in a lump, oftentimes at a most welcome moment, and, in many instances, of sufficient amount to render the average of former less profitable years sufficient to cover expenses, if not to leave a profit. There is likewise another inducement to breeding horses; we mean the interest inseparable from all human speculations, from which more than an ordinary return may be looked for, which is the case here; added to the nearly universal interest attached to the breeding and rearing of every species of domestic animals.

With respect to brood-mares designed for breeding hunters, we admit that circumstances, not always within control, have their weight. An occupier of land is possessed of a mare or two which he thinks *may* breed hunters, and having them, it may not be convenient to him to replace them by those which might be more likely to breed good ones. But the choice of a stallion is always within his control, and he should not spare trouble, and moderately increased price, in his selection. It is well known to all hunting men, that the stock of certain horses have been remarkable for making good hunters (we could name many of present and past times), and that there are such horses always to be found, on seeking for them. A few pounds extra, laid out by the breeder in putting his mares to such horses, are sure to be amply repaid; for the produce would be generally sought after and purchased, even previously to their being tried. Englishmen know of no such restrictions, nor do we wish they ever should; but the interference of the governments of several European states as to stallions for the use of their respective countries, reads us a useful lesson on this head; for it is well known, on the other hand, that a great number of stallions to which English hunting mares have been put, have been equally remarkable for begetting soft infirm stock, quite unequal to endure, for any length of time, the severe work of a hunter. It should also be borne in mind, that even a first-rate racer may not be a propagator of first-rate hunters. The former is called upon to exert his powers on very different ground, and under very different weight to the latter, and the action which may suit one may not suit the other. This accounts for the stock of certain thorough-bred horses, which were very indifferent racers, proving very excellent hunters. We have already given it as our opinion, that a cross of Arabian blood is a great desideratum in that of an English hunter, and we need not urge this point farther; but if breeders would reflect, that the expenses of rearing a bad colt equal those of rearing a good one, they would attend more than they do to the following nearly unerring directions.

First, Observe similarity of shape in horse and mare. As length of frame is indispensable in a hunter, if the mare be short, seek for a stallion likely to give her length. Again, if the mare be high on her legs, put her to a short-legged stallion, and *vice versa;* for it is possible that even a hunter's legs may be too short, a racer's certainly may be. In fact, to form a complete hunter, it is necessary he should be more perfect in his shape than a racer, which will admit of imperfections that would quite disqualify the other.

Secondly, Look to constitution. As no description of horse endures the long-continued exertion that a hunter does, this is a point to be attended to. But it may be overdone. Horses of a very hard nature, very closely ribbed up, consequently great feeders, with large carcasses, seldom make the sort of brilliant hunter now the fashion in England. Besides, one of this description requires so much work to keep him in place and in wind, that his legs must suffer, and often give way when his constitution is just in its prime. Horses with moderately sized carcasses last longest; and, provided they are good feeders, will come out quite as often as they ought to do, and are invariably good winded and brilliant, if well-bred and of good form, with a few other requisites. We never saw a very closely-ribbed, large carcassed horse, brilliant as a hunter, and we know such form is not approved of in the race-horse.

Thirdly, and lastly, Let the breeder of any kind of horse be careful in avoiding either sire or dam that has proved constitutionally infirm. As has been already shown on very high authority, perfect or defective conformation is not more likely to be the result of a proper selection of horse and mare, than disease to be inherited from parents that have been constitutionally diseased. We could name stallions whose stock have been blind; others afflicted with splents, curbs, and spavins, and a mare which produced three roarers by three different sires. But it may be said, that splents, curbs, and spavins, are the result of malconformation of the parts. Granted; but avoid all such malformation which is quite apparent to the eye in a breeding stud. It may perhaps be carrying this objection too far, were we to say, we would not breed from a mare or horse, which had become groggy or lame in the feet, from diseased navicular joints. Had the feet been more vigorously constituted, perhaps such lameness might not have occurred; yet it is but too probable that here the predisposing cause may be traced to over-severe treatment, and not to constitutional defect.

We have already expressed a regret at the prevailing prejudice against mares as hunters, admitting, however, that they are not to be so much depended upon at certain periods as the other sex. Nevertheless, no year passes over our heads that we do not hear of mares eminently distinguishing themselves on the race-course, in the hunting field, and on the road. Indeed, the majority of the extraordinary feats performed on the road have been performed

Hunter.

by mares. As relates to breeding hunters, however, this prejudice against them is most injurious in two ways. First, it takes off so much from the value of a filly, as in few cases to leave the mere cost of breeding and rearing her; and, next, many a mare, which would have proved a capital hunter, had she been tried, and, as is reasonable to suppose, a capital brood mare as well, is lost to the hunting world by being sold for harness purposes; and then, if good, so ruined in constitution as to be totally unfit to breed from. On the other hand, were mares more generally used as hunters, all such as proved themselves good, that is, were they stout, and had the peculiar kind of action that enabled them to go well on deep ground, over ridge and furrow, and were good leapers, they might for the most part be relied upon for producing good ones to succeed them. It may likewise be observed that, as in this case, the risk would be diminished, more people would breed hunters than do at present; and it is very generally admitted, that, at this time, so great is the scarcity of young horses likely to make hunters, were it not for those annually imported from Ireland, the demand would far exceed the supply.

Next in importance to the judicious selection of sire and dam, is the rearing of the colt, which it is intended should make a hunter. It was the remark of a gentleman, who kept fox-hounds more than half a century, that " great part of the goodness of a horse goes in at his mouth," and nothing is more true. Nimrod, in his Letters on the Condition of Hunters (p. 223, first edition), says, " It is my confirmed opinion, that unless a colt be what is called ' deformed,' it is in the power of good keep, exercise, and physic, to make him what is termed ' a fine horse,' and one which will sell for a large price, either for harness or the saddle. No one who has not witnessed it, is aware of the improvement in shoulders, thighs, gaskins, &c. from good old oats, accompanied by regular work and proper riding." Breeders of hunters may be assured that such is the case; and that it is of little use to breed colts with the expectation of their making first-rate horses, unless they keep them *very well* in their colthood. They should also be treated *as horses* at a very early age. They should be ridden gently, and by a light man, or boy, with good hands, at three years old, across rough ground, and over small fences; and at four they should be shewn hounds; but they should only follow them at a distance, and after the fences are broken down; for, if put to take large leaps at that tender age, they are apt to get alarmed, and never make first-rate fencers afterwards. Above all things, avoid getting them into boggy ditches, or riding them at brooks; but they should be practised at leaping small ditches, if with water in them the better, in the middle of a field, the rider putting them at them in rather a brisk gallop. This gives them confidence, and, the natural result, courage. With respect to the use of the bar, and teaching colts to leap standing over it, the practice is now condemned, and the system of letting them become timber jumpers, by taking it, as it comes, in crossing a country, is preferred, the present rate of hounds not admitting of the time occupied in a standing leap.

Some sportsmen adopt, and we believe with good effect, what is termed the " circular bar." Every description of fence that a hunter is likely to meet with, is placed within a prescribed circle of ground, and in this is the colt lodged, the man who holds him standing upon a stage in the centre. As another man follows him with a whip, he is forced to take his fences at a certain pace; and, in a very short time, a good tempered colt will take them with apparent pleasure.

At five years old it is customary to consider a horse as a hunter; but we are inclined to demur here. It is true, that if a colt has been very well kept, on the hard meat system, he is enabled to go through a good day's work with hounds at five years old, being quite equal to a six-year old, which has been kept on soft food, and not sufficiently forced by corn; yet it is always attended with danger of injury to his joints and sinews, if not to his general constitution; and we cannot pronounce a horse to be a hunter until he has passed his fifth year. As muscular action, however, produces muscular growth, he should not be kept in idleness during his fifth year, but should be ridden to cover, or with harriers, before Christmas; and when the ground gets dry and light in the spring, a good burst with fox-hounds may not do him harm. We do not, however, consider any five-year old horse fitting or safe to carry a gentleman over a country, as he cannot be sufficiently experienced to take a straight line.

We have known some masters of fox-hounds who have preferred purchasing yearling colts, or weanlings, at Michaelmas, to breeding them for their own use. The classical reader cannot fail calling to his recollection here the practical lesson which Virgil, in his third Georgic, imparts on this head; neither can the purchaser of such animals do better than follow it to the very letter. Should he fix upon the one which, as he describes him,—

> " Primus et ire viam, et fluvios tentare menaces
> Audet, et ignoto sese committere ponti,"

he would be pretty certain of having in due time a first-rate hunter, that would turn his tail to nothing. Nor should the breeder overlook the poet's advice to keep his young stock well, if he wishes to have them in the high form (and can any thing be finer?) in which the one of his own choice is presented to us in this most splendid passage.

There are undoubtedly certain advantages attending purchasing yearling colts, with the view of making hunters of them. Such only may be selected as appear calculated for the country they are intended to cross, and the weights they will be called upon to carry; whereas, were the master of hounds to depend on the produce of his own mares, he might be disappointed in being able to select the number he would require to replace, in due time, the vacancies which occurred annually in his stud. We should consider the sum of thirty-five or forty guineas for a good colt, at weaning time, a fair remuneration to the breeder, and well laid out by the purchaser.

Previously to giving directions for the purchase of a full-grown hunter, we shall proceed to exhibit him in his highest form, although we are aware of the difficulty, on certain subjects, of conveying, clearly, an idea from our own mind to that of another. We shall, however, endeavour to make ourselves understood by describing each individual point. As to the form and shape of a hunter's head, as we do not ride upon it, it is not of much consequence, provided it be well hung on, and that is of the very highest importance, not only, as we have shewn in the race-horse, on account of his respiration or wind, but unless it be so, he cannot be pleasant to ride. Not only must his jaws be wide, but when we consider that the head of a horse hangs in a slanting position from the extremity of the neck, and that the neck itself projects a considerable distance from the chest, on the muscular strength and proper formation of the neck must also depend whether a horse be light or heavy in hand, and consequently pleasant or unpleasant to ride. A weak or loose neck may not be so material, as we have before observed, to the race-horse; he is generally ridden in a martingal, and in that case always; add to which, his race is soon run. Nevertheless, we like to see the neck of the race-horse rise out of the shoulder with a tapering curve, in which case he is pleasant to ride in his gallop, and, if a hard puller, his jockey has much more power over him than if his neck were loose and low. But, in a hunter, the proper position of his head is a *point of the greatest moment*, as without it his rider cannot handle him properly

H er.

at his fences; and if he be not a regular star-gazer, he is always dangerous to ride over a country. The proper junction of the head with the neck, and the carrying of it well or ill, depend chiefly on two particular muscles contained in the neck. The most important of these is called the splenius muscle, which constitutes the principal bulk of the neck above, and its action is sufficiently evident, namely, very powerfully to elevate the head and neck. The principal beauty of the neck, indeed, as well as the carriage of the head, depends on this muscle; and its ample developement is a point the sportsman should attend to in the choice of horses that are to carry him with hounds. A certain degree of muscularity of the neck is absolutely necessary in a hunter, and it is greatly promoted by good keep in colthood; also by delaying the period of castration till the second year, which should invariably be done, when the want of this muscularity is apparent in the first. It must, however, be observed, that there is a medium in this muscularity of the neck, although excess is the better extreme of the two; for when the neck of a horse appears, like that of a sheep, to rise out of the chest, and so far from being arched above, and straight below, is hollowed above, and projects below, such a horse is nearly worthless for any pleasurable purpose, as his head cannot, by any means whatever, be got into a proper place.

It has been said, that a horse with a long neck will bear heavy on the hand. We do not believe that either the length of the neck, or even the bulk of the head, has any influence in causing this. They are both counterbalanced by the power of the ligament of the neck. The *setting on* of the head is most of all connected with heavy bearing on the hand; and a short-necked horse will bear heavily, because, from the thickness of the lower part of the neck consequent on its shortness, the head cannot be rightly placed. The head and neck, however, should be proportioned to each other. A short head on a long neck, or a long head on a short neck, would equally offend the eye.

Although length of neck in a hunter is not desirable, length of shoulder is indispensable. Horses have raced well with short upright shoulders; but it is impossible that one so formed, however good he may be in his nature, or even in his general action, can be a safe hunter, and for this reason: A hunter is constantly subject, by down-hill leaps, leaping into soft ground, and getting his fore-legs into grips, or unsound ground, to have the centre of gravity thrown forward beyond the base of his legs; and it is more or less recoverable according to the length or shortness of his shoulder. By length of shoulder is meant obliquity of the scapula, or shoulder-bone, by which the point of the shoulder is projected forward, and which, added to the obliquity of the scapula, enables the rider to sit considerably behind, instead of nearly over the fore-legs, or pillars of support, which, on a short and upright-shouldered horse, he must do. One remark, however, must be made respecting the oblique shoulder. It is sometimes not sufficiently supplied with muscle, with which the upright shoulder generally abounds. We therefore recommend purchasers of young horses for hunters, to give the preference to what may *appear* coarse shoulders, nay, even inclined to be somewhat round, or flat on the withers, provided they are accompanied by the necessary and absolutely essential obliquity of the shoulder-bones.

The setting on of the arm, which should be strong, muscular, and long, is of much importance to a hunter. By the length of this part in the hare, as we have already observed, added to the obliquity of her shoulder, she can extend her fore-parts further than any animal of her size: in fact she strikes nearly as far as the greyhound that pursues her, by the help of this lever. The proper position of the arm, however, is the result of an oblique shoulder. When issuing out of an upright shoulder, the elbow joint, the centre of motion here, will be inclined inward; the horse will be what is termed "pinn'd in his elbows," which causes his legs to fall powerless behind his body; and he is seldom able to go well in deep ground. There are exceptions, but they are rare. A full and swelling fore-arm is one of the most valuable points in a horse, for whatsoever purposes he may be required; and although we have occasionally seen hunters with light thighs carry weight well, we never have seen it so carried by horses deficient in their arms.

Hunter.

If sportsmen were to see the knee of the horse dissected, they would pay more attention to the form and substance of it than they generally do. It is a very complicated joint, but so beautifully constructed that it is seldom subject to internal injury. Its width and breadth, however, when considerable, are great recommendations to hunters, as admitting space for the attachment of muscles, and for the accumulation of ligamentous expansions and bands, greatly conducive to strength. Below the knee is a point on which we will not say much here, as we have already alluded to it in our remarks on the race-horse. We mean the shank, or cannon bone, and its appendages. It can scarcely be too short in a horse that has to carry a heavy man; round legs are almost sure to fail; those of the hunter should be flat, with the back sinews strong and well braced. This constitutes what sportsmen call a "wiry leg."

The fetlock is also a complicated joint, and very liable to injury. In a hunter it should be large and strong. But as regards his action, the pastern is still more material, and also to his standing sound. Very few horses with short pasterns can go well in deep ground, and for this obvious reason: The action of the joint is destroyed by getting below the surface of the ground, and is of course sooner immersed than when it is longer. But a greater evil than this attends a short pastern. It is the predisposing cause of navicular lameness, particularly in horses carrying weight, owing to the foot being deprived of that elasticity which a longer pastern affords, and which consequently relieves the concussion on the foot coming to the ground in galloping and leaping, as well as on the hard road. Horses with short and, consequently, upright pasterns cannot be pleasant to ride, and they seldom stand many seasons' work. Excess in either should be avoided, but of the two, a hunter is less objectionable, from the extreme of length, than of shortness, in this most material part.

That the foot of the hunter should be wide, is also obvious to the meanest capacity, independent of its being the form most conducive to health. The nature of the ground he has to travel over requires at times the widest base he can present to it, as a foundation for his great bulk, and thus the farmer carries out his manure upon tender land, in a broad and not a narrow wheel cart. Xenophon relates, that certain people of Asia were accustomed, when snow lay deep on the ground, to draw socks over the feet of their horses, to prevent them sinking in it up to their bellies; and we know why an ox sinks less in soft ground than a horse does. It is because his foot enters it expanded, by means of the division of the claws, and when he draws it out it is contracted. The foot of the hunter, however, should not be too wide, or it may operate against his speed.

The position of the fore-legs of the hunter admits of more latitude than that of his hinder ones, or indeed of any other part of his frame. We have seen brilliant hunters standing in all positions and postures as regards their fore-legs. Some very much over the knees, that is, with the knees bent and projecting outward; many upon very twisted fetlocks, turning the toes out; and a few, though only a few, turning the toes in. In the human frame, a certain squareness in the position of the feet is consistent with strength, as we see in the statues of Hercules, but the

Hunter.

lightness of a Mercury is indicated by the direction of the toe outwards. This is to a certain extent the case with the horse. Although, if measured by the standard of perfection, his toe is required to be in a direct line with the point of his shoulder, yet we have seen and heard of some of the speediest and best racers and hunters, the position of whose fore-feet have deviated considerably from this supposed essential line; but the inclination of the toe outwards is so common in horses used for these purposes, that it can scarcely be called a fault. Indeed, some persons argue, that a leg so placed affords a broader base to the superincumbent weight, than when quite in a line with the shoulder, that is, provided the twist arises from the fetlock, and not from the setting on of the arm. Be this as it may, we are well assured that, provided the hinder legs and quarters are good, a hunter will admit of a considerable deviation from the true line in the fore-legs, and carry his rider brilliantly. It is well known, that a much more twisted fore-legged horse could not well be seen, than the celebrated Clipper, the property of the equally celebrated Mr Lindow, for many years said to be the most brilliant hunter in Leicestershire.

But there is one portion of the fore-quarters of the hunter to which a rule must be applied, that will not admit of an exception. He must be deep in his chest or brisket, that is, from the top of the withers to the elbow. Numerous are the narrow, but deep horses, in their "girth," as the term is, that have carried heavy weights in the first style with hounds; but no matter how wide a horse may be, if he have not depth, he cannot carry weight, and is very seldom a good-winded horse, even under a light man. One of the greatest compliments, then, that can be paid to a hunter, at first sight, is, that he appears two inches lower than he really is. Such, however, is the case with horses whose growth has been forced in their bodies by good keep when young, and thus they come under the denomination of "short-legged horses," so much esteemed by hard riders. They are likewise, for the most part, better leapers than such as have less growth in the body, and stand upon longer legs.

We have before observed, when speaking of the race-horse, that large bone is not required in his cannon or shank (the part from knee to fetlock), neither is it in the hunter. The real power of all animals is in the muscles, sinews, and tendons; and the leg best calculated to carry weight and endure to a good old age, is that in which the bone is small, but of a dense and perfect texture, and in which three convexities can be very plainly distinguished, namely, the bone; the elastic ligament behind the bone, called the sinew; and, behind that, *the flexor tendons, large, round, and strong.* The rare combination of strength, with lightness, is here beautifully displayed, and is one of the many instances which might be produced, to show how Nature delights to work with the least possible expense of materials.

The hunter should have length in his shoulders and quarters, and, to a certain extent, also in his back. It is true that horses with short backs carry weight best up a steep hill, which, as that is the worst method in which this animal can employ his strength (in man it is the best), shows that heavy men should ride short-backed horses. For hunters, however, that are ridden in our best hunting countries, which, previously to being laid down in grass, were thrown up by the plough into high ridges, with deep furrows, must have *moderate* length of back, or they cannot go smoothly over such ground. Good loins, with width of haunch (the *vis a tergo* being so necessary in leaping, as well as gallopping on soft ground), need scarcely be insisted upon; and we now proceed to the hinder-legs, the proper or improper form of which makes the difference between a good or bad hunter, if a horse with badly formed hinder-legs can be called a hunter at all. But a horse with short, straight, and weak thighs, cannot make a *good* hunter. Even admitting that they are not weak, but short and straight, yet the objection remains, because he cannot, in the latter case, be pulled together in his gallop, nor have his stride collected to enable him to take his fences properly; and, what is not generally known, he is almost certain to be a hard puller. Indeed, some good judges go so far as to assert, that horses with straight hinder legs, never have good mouths, and there is much truth in the remark, as their form will not admit of their being "pulled together," as the horseman's term is, in their quick paces, and without it no horse is safe. A long and muscular thigh, then, with a clean well-placed hock, is one of the most material points in a hunter, and also one by which the duration of his services may very nearly be measured; as when much out of the true form, either inclining inwards, like the cow, or outwards, like the bandy-legged man, disease is almost certain to attack this very complicated but beautifully contrived joint, when put to severe exertion, especially in soft ground. The shank-bone of the hinder leg, below the hock, ought to be equally well supported by sinews and tendons with that of the fore-leg; and the pastern of the hind-leg should resemble that of the fore-leg, moderately long, strong, and oblique.

But such is the paramount importance of the hock in the hunter, that we transcribe the following admirable description of one most material point in it, (from Part IX. of "The Horse," Farmer's Series, p. 272.) "The most powerful of the flexor or bending muscles are inserted into the point of the hock, or the extremity of the os calcis; and in proportion to the projection of the hock, or, in other words, the length of this bone, will two purposes be effected. The line of direction will be more advantageous, for it will be nearer to a perpendicular; and the arm of the lever to which the power is applied will be lengthened, and mechanical advantage will be gained to an almost incredible extent. Suppose this bone of the hock to be three inches in length, the joint formed by the tibia and the astragalus is evidently the centre of motion, and the weight concentrated about the middle of the shank is the obstacle to be overcome. If the weight be four times as far from the centre of motion as the power, a force equal to four times the weight would raise it. It is, however, here to be remembered, that it is not merely the weight of the leg which is to be raised, but the weight of the horse, for the time resting upon the leg, and that weight to be propelled or driven forward. At what shall we calculate this? We may fairly suppose that the muscles, whose tendons are inserted into the point of the hock, exert an energy equal to 4000 lb. Let us further suppose, that an inch is added to the point of the hock, which will be an addition of one-third to its length: a muscular power of less than 3000 lb., will now effect the same purpose. The slightest lengthening, therefore, of the point of the hock will make an exceedingly great difference in the muscular energy by which the joint is moved, and a difference that will wonderfully tell in a long day's work. On this account, the depth of the hock, or the length of the bone of which we are speaking, is a point of the greatest importance. There is, however, a limit to this. In proportion to the length of this bone, must be the space which it passes over, in order sufficiently to bend the limb; and in that proportion must be the contraction of the muscle, and consequently the length of the muscle, that it may be enabled thus to contract; and, therefore, if this bone were inordinately lengthened, there would require a depth of quarter which would amount to deformity. A hock of this advantageous length is, however, rarely or never met with, and it is received among the golden rules in judging of the horse, that this bone of the hock cannot be too long."

Hunters which carry very heavy men cannot excel in

H ter.

the field, unless they exhibit those just proportions in their limbs, and all the moving levers, necessary to produce full liberty of action, but not too long a stride. Well placed hinder legs, with wide hips, well spread gaskins, and great depth of chest, are essentials, and as much of the *vis a tergo*, as is consistent with a not unsightly back, commonly called "hog-backed." Well knit joints, short cannon bone, moderately oblique pasterns, with rather large feet, are not only points from which great physical powers may be expected, but they are necessary to the duration of them in the horse we are now alluding to. As, however, it is an axiom in the animal creation, that the parts which add to strength diminish swiftness, hunters to carry more than sixteen stones well with hounds, at the pace they now run, are always difficult to be procured, and ought to command good prices. The stamp of animal most approved of for this purpose, is the short-legged, thick, but well-bred horse, not exceeding sixteen hands in height, but appearing, to the eye, half a hand below that standard. As for his general appearance, it is "handsome is, that handsome does," in this case; and we must not look for beauty in all his points.

Having now described each individual external part of the horse essential to his being a good hunter, we shall, in a few words, exhibit him to the reader's view in what we consider his best form. He should have a light head, well put on, with a firm, but not a long neck; lengthy, and consequently oblique, shoulders, with very capacious chest, and great depth of girth; a long, muscular fore-arm, coming well out of the shoulder, the elbow parallel with the body, neither inclining inward nor outward; a short cannon or shank, with large tendons and sinews, forming a flat, not round leg; an oblique pastern, rather long than short, and an open circular foot; the back of moderate length, with well developed loins and fillets, and deep ribs, making what is termed by sportsmen a good "spur-place." From the loins to the setting on of the tail, the line should be carried on almost straight, or rounded only in a very slight degree. Thus the haunch will be most oblique, and will produce a corresponding obliquity in the thigh-bone, which formation is peculiarly characteristic of the well bred horse. The dock of the tail should be large, the buttocks close together, and the fundament small, and somewhat resembling the front or eye of the pippin apple. The thighs should be muscular and long, rather inclining inwards, with large lean hocks, the points appearing to stand somewhat behind the body, which will bring the lower part of the hind-leg, or shank, under it. The shank, fetlock, and pastern of the hinder-leg, should exactly resemble those of the fore-leg, as also should the foot. The legs should appear short, from the great depth of chest, and well-proportioned substance of the body, or middle-piece.

The stature of the horse is no more absolutely fixed than that of the human body, but a medium height is considered as best for a hunter, say fifteen hands, two or three inches. For one good horse over this height, there are a hundred under it. In fact, there are, in the operations of nature as well as of art, limits which they cannot surpass in magnitude, and it is known that no very large animal has strength in proportion to its size. That the horse has not, the pony affords proof, if any other were wanting. Even the heaviest weights find horses about the height we have fixed upon best calculated to carry them. There have been many extraordinary instances of horses, little more than fourteen hands high, being equal to the speed of hounds over the strongest counties in England, for example, Mr William Coke's "Pony," as he was called, many years celebrated in Liecestershire; but they are not pleasant to ride, by reason of the fences, when high, appearing higher to the rider than when he is mounted on a taller horse.

Hunter.

Temper and mouth are essential points in a hunter. The former adds much to his value, not only as it contributes to the pleasure and safety of his rider, but a horse of a placid temper saves himself much in a long day's work with hounds, and especially when there is much leaping. Indeed, fretful horses are proverbially soft, and not generally to be depended upon at a pinch, which caused Shakspeare to make them the symbol of false friends. Thus Julius Cæsar exclaims,

> "Hollow men, like horses, not at hand,
> Make gallant show, and *promise* of their mettle;
> But when they should endure the bloody spur,
> They fall their crest, and, like deceitful jades,
> Sink in the trial."

A hunter should have courage, but nothing more, to make him what he is required to be, namely, not afraid to leap at any fence his rider thinks proper to put him at. His mouth will depend upon two things; first, upon the judgment of the person who breaks him in, in his colthood, and, secondly, upon the position of his hinder legs, but chiefly upon the first. It ought to be endowed with so great sensibility, that the slightest motion of the bit should give him warning, and direct his course, which is significantly implied by Horace, when he said, "the ear of a horse lies in his bridle." It is true, that what we call the "mouth" of a horse, is an artificial feature, at all events, a figurative term for his being easily acted upon by the bridle; but it is a point of the utmost importance in a hunter. Without it, in short, he is absolutely dangerous to ride; for although the skill and power of his rider may prevent his running away, yet he is always in danger of being placed in some unpleasant situation or other by him. In the first place, he cannot be a large fencer, nor safe at all sorts of leaps, if he will not suffer his rider to pull him together, to collect him for the effort of rising at them. Secondly, he is as dangerous in going through gates, only partly opened. Thirdly, if the horse immediately before him should fall at a leap, he is very apt to leap upon him, or his rider; and, lastly, his strength is sooner exhausted than that of a horse, perhaps not naturally so good, which is going quietly, and within himself, by his side.

No doubt many of the ancient writers were good judges of horses, although they were deficient, compared with the moderns, in availing themselves of their highest capabilities. Were a purchaser of a hunter to look no further than the first chapter of Xenophon περι ἱππικης, he would find hints that would be well worthy his attention; and nothing can be more expressive of the evils attending a bad mouth, in a horse of this description, than the following sentence from Pliny, "Equi sine frænis deformis ipse cursus, rigida cervice, et extento capite, currentium," which may be thus translated: The career of a horse without a bridle is disagreeable, carrying his neck stiff, and his nose in the air. When we consider how often it is necessary to pull up, or to turn a horse very short in crossing enclosed countries, the value, even on the score of comfort, of a good mouth cannot be too highly appreciated by the sportsman.

We now come to the action of the hunter, which, after all, is the main consideration. He should have energy in all his paces, but he may have too much of what is generally called action. Nothing conveys to us a better idea of that which is adapted to his business, than the concluding sentence of a huntsman of former days, when describing to his master a capital run with his hounds. "The old mare," said he, "*carried me like oil.*" The action of the hunter should be *smooth*, or it will not last. His stride in his gallop should be rather long than otherwise, provided he brings his hinder legs well under his body; and the movement of the fore-legs should be round, but by no means high. Above all things, there should be no "*dwel-*

ling," as it is called, in the limb coming to the ground; a great obstacle to speed, but often the accompaniment of excessive action in the fore-legs. But the test of action in the hunter, is in what sportsmen call "dirt," that is, in soft, tender ground, or when passing over such as appears dry on the surface, but is not sufficiently so to bear his weight. It is not exactly in the power of the best judges to determine whence this peculiar excellence, which some horses possess over others apparently well-proportioned, arises, for which reason the eye should never be depended upon in the selection of horses for the field. Wisdom here can only be the produce of experience; and many sportsmen have paid dear for it on this particular point. In fact, nothing next to ascending steep hills under great weight, puts the physical powers of a horse to so severe a test as carrying a heavy man, at a quick rate, over a country that sinks under him at every step. Mere strength alone will not do it. It must be the result of a combination of strength with agility, good wind, and speed, to produce which, the most perfect arrangement of the acting parts, although the exact symmetry and proportion of them may not be exactly discernible to the eye, are requisite, and, we may be assured, are present. As the beauty of all forms is, in great part, subordinate to their utility, a horse of this description, that is, one which can carry sixteen stones well up to hounds in any or in all countries, at the rate they now run, not only, as has before been observed, commands a very high price, but, to a person who loves to study nature, presents a feast to the eye.

A hunter should be what is called very quick as well as very fast; by which is implied, that he should not only have great speed, but that he should be very quick in regaining his speed after taking his leap, or being pulled up from any other cause. One so gifted will cross a country, especially a close one, in less time than one that is more speedy, but not so "quick on his legs," as Jockies term it. It is also very agreeable that a hunter should be safe in his slow paces on the road; and, if a fast trotter, he relieves himself by changing the action of the muscles, when the pace of hounds so far abates as to allow him to break into a trot.

Leaping.

One of the greatest accomplishments in a hunter is being a perfect and safe leaper. The situation of a sportsman riding a horse that is "uncertain," as the term is, at his fences, may be compared with that of the philosopher which Cicero describes in his Tusculan Questions, (5. c. 21), as seated on the throne of Dionysius, gazing upon the wealth and splendour that surrounded him, with a naked sword suspended over his head by a single thread. But a horse following hounds often leaps under very great disadvantages, which accounts for the numerous falls sportsmen get. Putting aside the labour of rising from the ground, which, to the horse, with a weight on his back, must be great, from the earth's attraction and the body's gravity, he has often to take his spring without any fixed point for support; whereas, in most other cases, leaping takes place on a fixed surface, which possesses the power of resistance in consequence of its firmness. Nevertheless, although the surface yield to a certain degree, leaping can still be performed, notwithstanding the retrograde motion of the surface produces a great diminution in the velocity of the leap, compared with that which is made from firm ground; and the velocity is always greater in proportion as the resistance is perfect. Thus it is, that we find horses able to cover much greater obstacles in Leicestershire, and the other grass countries, where the taking off for the leap is generally good and sound, than they can cover in ploughed and marshy districts, where they have not that advantage, from the less firm state of the soil. We shall now endeavour to point out the form most likely to constitute a good leaper.

The very worm that crawls on the ground first carries its contraction from the hinder parts, in order to throw its fore parts forward; and it is chiefly from the *vis a tergo*, or strength of back, and hinder quarters, that the power of leaping in a horse is derived. It must, however, be admitted that oblique shoulders give him a great advantage, by enabling him to extend his fore quarters; but if his loins be loose and weak, and his hinder legs ill placed, with weak hocks, he cannot make, in any one's hands, a safe and perfect leaper. But the position of his head has something to do with it. A plank placed in equilibrio cannot rise at one end unless it sinks at the other; and although a horse in light harness cannot, for appearance' sake, carry his head too high, provided he be obedient to the rein, the hunter should carry his low. A colt, running wild, never raises his head when he leaps, but rather lowers it, and so should the hunter; and he is always less liable to fall in gallopping over a country when he carries his head low; likewise, in horses with lengthy shoulders, the seat of the rider is rather benefited than injured by it.

The sort of fence that stops hunters more than any other description of obstacle, is a wide brook; and, like all other wide places, it takes a good deal out of him, if he clears it. Lengthy horses are the best brook jumpers; but they require good loins and hinder quarters as well, and, above all things, *courage*. Unless a horse takes a wide brook in his stroke, he is almost sure to be in it; for which reason he is generally ridden fast at it, and, for the most part, not allowed to see it till he comes close to it. Immense space has been covered by horses when jumping brooks, particularly when there has been a difference of elevation of the banks in favour of the horse. We have heard of thirty feet and upwards from hind foot to hind foot; but half that space *in water* is considered a good brook, and even if the banks are sound, stops a great part of the field. When unsound, it requires a horse, coming under the denomination of a "good brook-jumper," to clear it without a fall, and particularly, if towards the end of a run.

To be a good timber leaper is a great desideratum in a hunter, although many horses are great timber leapers, but, from their form, can never make good hunters. It only requires a short backed, truss-horse for this purpose; and he can dispense with the general length so necessary to the complete hunter. Good and well-formed thighs, however, are necessary. For those hunting countries, such as Cheshire, where the hedge is generally placed on a bank or "cop," as it is there styled, rather a short but very active horse performs best. But he must be very good in his hinder legs, and very quick in the use of them. Wall jumpers come within the same class with timber jumpers as to make and shape.

There is one faculty in which the horse is wanting, that would, if he possessed it, give him a great advantage in leaping. In the human species, the power and influence of feeling are inherent, in a great degree, to the very tips of the fingers; but the horse has no proper organ of feeling or touch. When a man takes his spring for a leap, or leaps on the top of any substance, he has a distinct and certain sense or knowledge of the nature of the ground from which he has sprung, and of the substance on which he has alighted; but, from the insensible nature of the horse's hoof, such feeling is, in a great measure, denied to him, and indispensably so too. Still, however, there are a few instances upon record of horses going very well over a country even after having undergone the operation of neurotomy, by which all sensibility, from the fetlock downwards, has been destroyed.

Looking at the pace of hounds, and the manner of riding after them, which have so materially changed within the last half century, it is insisted upon by some that the hunter of the present day ought to be of full blood. Reasoning from analogy indeed, between the powers and capabilities of one and another, we are decidedly in favour of that breed which has the greatest share of strength within the smallest compass, and such is decidedly the character of the thorough-bred horse. Independently of this, the thorough-bred horse, when perfect, and with substance, is peculiarly fitted for what a hunter is called upon to perform; and those persons who assert to the contrary, can only do so in ignorance of the nature of his constituent parts. He has more depth and declivity in the shoulders than the lower bred horse has, and is consequently clearer in his wind. By these means, he can better extend and elevate his fore feet in going over rough ground, and at his leaps; and, by the curve or circular figure he makes with his hinder legs, he stands more secure on all kinds of ground, and, above all things, he bears being pressed better than any other description of horse; for, although blown, he soon recovers his wind. Having said this, it may scarcely be necessary to add, that several of our first-rate sportsmen of the present day will not ride any thing that is not of full blood; and such description of horse, when perfect in his work, as well as in his form, commands the highest price.

Nevertheless, the *necessity* for the thorough-bred horse in the field is belied, by the experience of all unprejudiced sportsmen, and even in Leicestershire, where the best studs are to be found, not a twentieth part of the hunters are of that description. But this perhaps arises from three causes. First, there is a difficulty in procuring full-bred horses to carry even moderate weights, and speed is but a second attribute to a hunter. He must have sundry other qualifications, and the most prevailing objections to the thorough-bred horse are generally these: He is apt to be deficient in substance to carry high weights over rough and deep countries, without trespassing too much on the virtue of his high descent. Secondly, he is inclined, and especially if he have been trained, to be shy of facing rough and thorny fences, by reason of the delicate nature of his skin, rendered so by repeated sweats in clothes, when in training. It often happens, indeed, that even the cheering influence of hounds, which has so much effect on other horses, will not induce him to take them. In fact, which may appear extraordinary, he does not appear to have in the field the courage of the half-bred horse. Lastly, his feet are apt to be small, in which case he sinks deeper in soft ground than does the lower-bred horse, whose feet are larger and wider, and thus suffers more than the latter does, in crossing a deep country. As for his powers of endurance under equal sufferings, they doubtless would exceed those of the cocktail, and being, by his nature what is termed a "better doer" in the stable, he is sooner at his work again than the other. Indeed, there is scarcely a limit to the work of full-bred hunters of good frame and constitution and temper.

A sportsman, partial to thorough-bred hunters, should either breed them, or purchase them, not exceeding two years old. If he breeds them, he should select large and bony mares, putting them to horses who have hunting action, such as Tramp had, and several more we could name; and, if he buy them, it will be his fault if he do not buy those of the right stamp. From their never having been trained, but ridden over rough ground in their colthood, they would have freer and higher action, and, when castrated at a proper age, would very rarely fail making first-rate hunters. But it may be asked, why subject them to the enervating operation of castration, which, as Perceval says, stamps their form and character with the seal of imbecility and pusillanimousness? Our answer here is, that we would not do it, if experience did not shew that by far the greater number of entire horses, used as hunters, are either dangerous in a crowd, and when pressed upon in gateways; or given to refuse their fences, when they feel themselves somewhat distressed; and, if once well tired, are not to be depended upon afterwards. When free from these defects, they are doubtless superior to either geldings or mares.

Purchase of a Hunter.

Although it may not be necessary that a person should be perfectly acquainted with the mechanical structure of the horse's frame, according to the laws of nature, to render him a good judge of a hunter, yet, fortunately for such as have them to sell, vast numbers of persons purchase hunters from very slight experience of them, regardless of the proverb of, "he hath a good judgment who doth not rely on his own." There is also another proverb, prevalent, we believe, in Spain, which well applies here:—"He that would buy a mule without a fault must not buy one at all;" and, although faultless hunters may be as rare as faultless riders of them, we will offer a few hints to a person in the act of purchasing one, addressing him in the colloquial style.

First, bear in mind the country you are about to hunt in, whether flat, hilly, firm, soft, open, or enclosed, and refer to the remarks we have made on the sort of horse we have adapted to each; only be assured that in an open country, especially if a hilly one, nothing has a chance with a thorough-bred horse, in good form, and not over-weighted. Secondly, consider well your weight, and be sure to have at least a stone to spare. A light man on a light horse throws away all the advantage of being light, and can go no faster, or leap larger fences, than a heavy man on a strong horse, *for strength will be served.* Until you try him, it is hard to say what horse will make a hunter, but the following indices may induce you to try him: If he appear well-bred, with a loose, bright skin, which may be called his complexion; observe that his hair does not stand hollow from the skin, particularly about the poll of his neck. If you find him standing over a good deal of ground, it is a sure sign that he has got length where it ought to be; not in the back, but from the obliquity of his shoulders, and the arm being set on at the extreme point of his shoulder, which so much contributes to the act of extension of the fore parts in gallopping, leaping, and clearing grips. Next examine minutely his thighs and hocks, being especially careful to observe the position of the point of the hock bone. Above all things, avoid a short, or an overtopped horse. The former will never carry you to your satisfaction, however good he may be in his nature; and the latter, from being too heavy for his legs, will seldom last many years. As for the minor points, common observation alone is wanting. Have his head placed in such a situation as will enable you to satisfy yourself that he has perfectly organized eyes, free from incipient cataract, sometimes rather difficult to be detected; and as for his age, there are but two ways of satisfying yourself on that point. By his teeth till about eight years old; afterwards by the state of his legs, which are, in fact, the best test of his value, the best proof of what he has done, and the sure source of speculation as to what he may hereafter be expected to do. Observe, also, his joints, that no material injury has been done to them by blow, &c., and that they are strong.

But the purchaser of a hunter must not trust to his eye. Neither must he be satisfied with him, how well soever he may gallop with him upon *sound* land. It is the peculiar excellence of "going well through dirt" that renders a horse valuable for all our best hunting countries; and no man can assure himself that a horse has this peculiar excellence, until he puts him to the test. The best method of doing it is this: The rider should put him along at a

Hackney.

good pace, with a slack rein, upon sound ground, letting him find himself all at once upon that which is soft and holding. If, on quitting the former, he cringes more than might be expected under the weight, and shortens his stroke much, he must not purchase him for a hunter. He may go well over a light, down country, but he will never distinguish himself over a heavy one, as he will be going in distress, when other horses are going comparatively at their ease. Horses possess gradations of excellence in this natural qualification, or gift, more than in any other, but in it consists the *summum bonum* in a hunter; inasmuch as, whatever may be his other good qualities, they are all useless, when the acting parts are, from this cause, deep ground, easily over-fatigued. With regard to his wind, he must not judge hastily of that, in a horse not in work. Should he not perceive any thing like whistling in his respiration, when he puts him along at a quick pace, and his chest is capacious and deep, and his head well set on, he is not to reject him, in case he appears blown by a short gallop. Condition and work will rectify that; but many a good hunter has been rejected on this account, by persons not taking into consideration the state of his bodily condition, in a trial of this nature.

The price of the hunter varies with the times, and, no doubt, is as much regulated by the price of wheat as the quartern loaf is. During the war prices, the sum of a thousand guineas was occasionally given, and that of five hundred guineas frequently. Half the last-mentioned sum now commands a first-rate hunter. But first-rate horses, in all ages of the world, have ever produced extravagant prices. It is recorded of Alexander the Great, that he gave four Roman talents for Bucephalus, which approaches near to the Melton Mowbray prices, and those, we may safely conclude, stand at the head of the list.

THE HACKNEY.

Under this term are comprised the following: The Cover Hack, the Park Hack, the Lady's Horse, the Roadster, the Cob, the Galloway, and the Pony.

The difficulty of procuring really good hacks is admitted by all persons who have kept them for the various purposes of either business or pleasure, and for the following obvious reasons. First, very few people try to breed hackneys, therefore, although we require them to be nearly perfect in shape and action (and perfect they should be to be "really good hacks"), they may be said to be failures in the breeding stud after all. Secondly, by reason of their appearing to be failures in their colthood, they are not forced into good shape, as more promising young horses are, by high keep and care. Lastly, If a man has a really good hack, he is unwilling to dispose of it at the price generally given for such animals. But a question arises, What is a good hack? It cannot be answered but with reference to another question, namely, What description of person is he to carry? The horse that a sober citizen of London or Edinburgh would call a perfect hackney to carry him to his country seat, would not be worth five shillings to a Newmarket or a country jockey, or as a cover hack to a Leicestershire or Warwickshire sportsman. We will commence, then, with the cover hack, and describe the others in their turns.

The Cover Hack of the present day is very difficult to be procured, because he must unite, with the good qualities of the roadster, the requisites and accomplishments of the hunter. In fact, he must be a hunter in miniature; and, after all, the form of the hunter is the best calculated for a roadster. He must be fast in all his paces, able to gallop well on deep or soft ground, and equal to carrying his rider over moderately-sized fences; and if taught to leap timber, standing, his value is proportionally increased. But, above all things, he must go from twelve to fifteen miles in the hour, when wanted, without showing any symptoms of distress; and he is too often unnecessarily called upon to perform much more than this, by his owner delaying the period of his leaving home in the morning, for the purpose of meeting hounds. It may also be observed, that it is not every sportsman who keeps two cover hacks, although he may keep six or eight hunters; and it often happens that the cover hack does more work than any horse in the stable, although in justice it should be stated, that the same care in the stable is now taken of him as of the best hunter in it.

Unless to carry a great weight, the cover hack should be all but thorough-bred, if he cannot be procured of quite full blood; with excellent legs and feet, lengthy and elevated shoulders, and with a susceptibility of mouth that will not only enable his rider to keep him well on his haunches, to guard against danger when going fast on all sorts of roads, but as tending to lessen the fatigue of riding him; and the strength of his rider should be reserved for his day's diversion after hounds. The chief pace of a cover hack should be the canter, and his temper should not be overlooked, for if fractious, and a puller, he will add much to the fatigue of a severe day's sport. A horse of this description, nearly fifteen hands high, young and sound, will command from sixty to a hundred pounds. The other points essential to a good road hackney, which will be noticed hereafter, apply equally to the cover hack.

The Park Hack of the present day is the race-horse in miniature. To be quite *à la mode*, he should be thorough-bred, with a very neat head, beautifully set on, and a switch tail; and so well bitted as to be ridden with a slack rein. He should have much liberty in his walk, which, and the canter, should be his chief paces. He must have great obliquity of shoulder, with a corresponding true formation of hinder quarters, and above all, the well-bent hinder legs; in which case, if the position of his fore-legs enable him to put his feet down properly, which will be explained in describing the general action of the hackney, he will be, if good tempered, and not given to fret, the perfect park hack.

The Lady's Horse is, after all, the most difficult to obtain, because he ought to approach very near to perfection. His paces, mouth, and temper, should each be proportioned to the power and capability of his rider; and he should be proof against alarm from either noises or sights, which otherwise might cause him to run away. This description of horse should likewise be well bred, as in that case his action will be easier, and his appearance and carriage more in character with the generally elegant appearance of his rider. His pace should be the canter; the trot causes an ungraceful movement in the person of a woman, to enable her to rise to it; and if she do not rise to it, she is much shaken in her seat. Neither is the form of the side-saddle fitted for the trot; and the canter of a well-bitted horse is more safe, because his haunches are more under him in that pace than they can be in the trot. A good, bold, walk, however, with the head in proper place, is essential to a horse that has to a carry a woman; and his action should be very true, that is, he should not "dish," or throw his legs outward, as the term is, in any of his paces, or he will cover the lower garments of his rider with mud when the roads are wet and dirty. To provide against the latter inconvenience, however, all horses intended for this purpose, should not be much under fifteen hands and a half in height, which size corresponds with the lengthened drapery of a lady's riding costume. As a preventive against accidents, ladies' horses, however well broken and bitted, should not be too highly fed; and, if at all above themselves, should be ridden by a careful servant, with good use of his hands, before ladies mount them. It is, however, an acknowledged fact, that horses go more quietly under women than they do under men, which is accounted for by the lightness of their hand, and the backward position of the body, in the saddle. We have, in fact, known several instances of horses being very hard pullers with men, standing up in their stirrups, and, consequently, inclining their bodies forward, but going perfectly temperate and at their ease under women.

The power and parts conducive to action in the roadster, or hackney, are derived much from the same shape and make as we have shewn to be best fitted for the hunter; but it is desirable that he should be more up in his forehand than the hunter is required to be, as such form gives confidence to the rider. *The most dangerous* form he can exhibit, if we may be allowed such a term, is, with his fore-legs standing too much behind the points of his shoulders, *and those points loaded.* Even with the best-formed hinder legs, the centre of gravity being thrown so far forward beyond the pillars of support, is, in this case, with great difficulty preserved on the horse making a stumble; but with straight hinder legs, a horse so formed in his forequarters is only fit for harness, where he can recover himself by the assistance of his collar, having no weight on his back. Provided a hackney do not cut his legs, by striking one against the other, which is oftener caused by imperfection in the upper than the lower extremity of the legs, he is not to be rejected because he may turn out his toes a little, some of the very best, fastest, and safest road-horses being so formed. Cutting the hinder legs is a worse failing than cutting the fore ones, as it is a certain sign of weakness; and although we may be told that shoeing will prevent it, we bring to our recollection the old adage, that "a goose always goes like a goose." What is called the "speedy cut" with the fore-legs, arises from excess of action, and is a great objection, by reason of the wound given to the leg, which is struck just under the knee. Many good hunters, especially when ridden in hilly countries, such as parts of Surrey, where they traverse the hills on loose and stony ground, are subject to this failing, which is remedied by a boot; and, after all, the danger attributed to speedy cut, in throwing horses down, is much overrated.

The size for a road hackney must be regulated by the size of the person to ride him; but, generally speaking, from fourteen hands to fourteen hands and a half, is the proper height. His strength must also be thus calculated, for a light man does not ride pleasantly on a horse equal to double his weight. But a road hackney should have strength of shoulder, with a round barrel, but not a large carcass, which only wears out his legs. His constitution and feeding can only be proved upon trial; but there are certain indices, such as deep ribs, hardy colour, brown muzzle, &c. which very rarely deceive us. As to the necessity of well-placed hinder legs, it is most clearly shewn by the answer given to the following question: If a horse make a serious blunder forward, and the centre of gravity of his body fall beyond the pillars of support, and is for a moment lost, what restores the equilibrium? Is it merely the chuck under the chin to an animal of his bulk and weight, and that "chuck" given perhaps by the weak, powerless wrist of a feeble old man, or delicate young lady? No: the main effect of the bit, or curb, in this case is, first, warning the horse of his danger; and, next, by the momentary raising of his head, he is better able to bring a hinder leg *instantly* to his assistance, by advancing it under his body, and thus restoring the equilibrium. In the walk, in fact, the horse actually begins to move by advancing the hinder-leg under the body, before the fore-leg quits the ground; and if he did not do so, there would be no equal support for the body, during the suspension of the fore-leg in the air; nor could the body be moved forwards, until the hinder leg had, by quitting its station, taken a new point of support. Seeing then, that in the walk, as in all other paces, the centre of gravity in the horse is maintained, as well as the body propelled, by the action of the hinder legs, the greatest attention should be paid to the position and action of them in the hackney, as the best safeguard against his falling. We should observe, then, when he is exhibited to our view, that, in his walk, the hinder foot oversteps the fore foot, at least a shoe's length, which a horse with straight, ill-formed hinder legs cannot do; and if such action be accompanied by generally good hind quarters, it is a great indication of safety, as far as one-half of the body of the horse is concerned. But as the false step is made, not with the hinder, but the fore leg, the chief safeguard against falling is to be found elsewhere, namely, first, in the length of the shoulder, which throws the centre of gravity further back than a short one; and, secondly, proceeding also from the free use of the shoulder, in the act of setting the fore-foot down on the ground. It is a general but very mistaken notion, that the safety of a roadster depends upon his lifting his fore-feet high from the ground, when he is said to "go well above his ground;" whereas it all depends on the manner in which he places them down upon it. Not only are the highest goers often the most unsafe to ride, for, when they do fall, they fall with a violence proportioned to the height of their action; but, although we do not advocate such extremes, there are thousands of instances of horses going *very near* to the ground, and never making a trip. It is, however, a well established fact, that if the form of a horse's shoulder, and the position of the fore-leg, enable him to put his foot to the ground *flat*, with the heel well down, his lifting up his foot high is not at all necessary; whereas, on the other hand, if, by an improper position of the leg, issuing out of a short, upright, ill-formed shoulder, the toe touches the ground first, and, as it were, digs into it; no matter how high such a horse may lift up his leg, in any of his paces, he will always be dangerous to ride. And this will be clearly shewn, if we consider the position of the fore-leg, when off the ground, or in action. It is bent in the form of a *C*, and the foot suspended in the air, turning inwards, with a curve towards the body. When in this state, were the foot to come in contact with a stone, or any other substance, it would pass over it without resistance, the limb being at that time in a flaccid state; but when it approaches the ground, the limb being extended, and having the whole weight of the fore-quarters about to be thrown upon it, if it strike against a stone, or any hard substance, then the case is greatly altered, and a stumble is the inevitable consequence. The base now requires to be firm and even, which it can only be by the foot being placed flat upon the ground. Man, in fact, walks very near the ground, but his toe rarely strikes it. If it did so frequently, he would soon become a cripple, putting falling out of the question. His action proceeds from his hips; that of the horse, as regards the fore-legs, from his shoulders; but the principle is the same with each; each is a piece of curiously-wrought mechanism, and according to the correctness of that mechanism is their action true. A wrong notion, however, prevails here, which may lead the purchaser of a hackney astray. It has been asserted by various writers, that, if the shoe of a roadster be found worn at the toe, it is a sure sign of his possessing the dangerous action to which we have alluded. This is false; many horses wear at the toe, solely by the act of picking up the foot, and quite independently of placing it down. That many hackneys, however, fall from their shoes being neglected and suffered to wear too much at the toes, we are well aware, as well as from their pressing upon the heels and quarters, from the want of being removed in proper time. When a horse is given to wear at the toe, the wearing part should be steeled.

The best method of ascertaining the manner of putting down the foot, on which we have shewn the safety of a hackney depends, is, to ride a horse with a slack rein, on a footpath, on which there are trifling undulations, scarcely perceptible, but sufficient for our purpose. If he walk smoothly over such ground, and do not strike it with his toe, we may be sure he puts his foot properly down, and will not, from that cause, be a tumble-down. But there are various ways in which horses fall on the road; bad shoeing, as we have already said, being one of them, and bad condition another. What is called a false step, very different from a stumble, may occur to any horse, and is occasioned by his accidentally putting his foot on a loose stone, that rolls away from under it, when, of course, his footing is lost. In this case, his chance of recovering himself is in his shoulders being oblique and lengthy (for upright shoulders are always short) and well placed hinder legs. Thrushes and corns are likewise the cause of stumbling; as likewise is starting, one of the worst failings a hackney can have. In some horses it is a nervous affection, rather difficult to account for in animals of such strength of frame; and often arises from imperfectly formed eyes, such as flatness of the cornea, or outward surface of the eye, generally a small one, causing short-sightedness. In the latter case, this fault in a hackney may be guarded against, by employing a veterinary surgeon to inspect him previous to purchase.

The old adage of "No foot, no horse," applies particularly to the road-horse. The hunter can cross a country upon feet that are very far from good; and by the help of bar-shoes, the coach-horse, with no weight on his back, and with the support the harness gives him, gets pretty comfortably over his stage on unsound feet; but the road-horse must have sound feet. Previously to the use of horse-shoes, the value of a solid hoof was so great as to have been made the image by which the Prophet Isaiah set forth the strength and excellence of the Babylonish cavalry, "whose hoofs," says he, "shall be counted as flints." Both Homer and Virgil mention it as an indispensable requisite in a good horse, the latter making it to resound as it strikes the ground,

> " ——— et solido graviter sonat ungula cornu."

We are not going here to enter on a long discussion upon the foot, but only to observe, that the wide hoof and expanded heel of the hunter is not so essential to the road-horse as many persons suppose. Indeed the hoof that has been found to stand *severe* road-work best, is one rather high at the heel, and not very wide, provided the pastern above do not approach too near the perpendicular; forming what is called "an upright pastern," which, by the jar the foot receives from it, when it comes to the ground, is nearly certain to produce disease. The strong foot, however, of which we are speaking, is one that requires care, by being frequently drawn out with the knife, to prevent its becoming too strong; and by giving moderate pressure to the frogs, to prevent the heels getting nearer together than we find them, and they already approximate to contraction in a foot of this description. The just form of the hoof in front, upon which mainly depends its form behind, is said by Clarke to be at an elevation from the ground of thirty-three degrees,[1] and we are inclined to think, that a much greater elevation than this would approach too near the perpendicular, for any kind of foot. As the inner heel or quarter has more weight thrown upon it than the outer, it is the principal seat of corns and sandcracks, for which reason great care should be taken that an even bearing to the whole of the crust be given by the smith to the foot of the hackney, previously to his setting on the shoe, the inner heel being given to wear away more than the outer on that account.

In the action of the hackney consists his chief merit. It should be smooth, and with not too long a step, or stride, or he will tire. He should also go straight on his legs, as the term is; for although horses that dish their legs may be, and commonly are, safe goers, yet they are disagreeable to ride in wet roads, as they cover the rider with mud. As we have already observed, the action of a hackney should not be high, as that tends to fatigue the rider and destroy himself; and if he puts his foot well down on the ground, he will never fall by reason of his action being low, and he will last the longer for its being low.

The paces of the hackney are in a great measure dependent on the will of his owner. The walk and the canter are most essential to what may be called the pleasure hackney; but for general purposes, the trot is the most useful and available pace in a roadster, and one in which he will continue longer, according to the rate he is going at, than in the canter. There are instances, however, and here is perfection in a hackney, of horses with very oblique shoulders, and excellent hinder legs, being able to carry their riders in a canter, over every variation of road, down-hill, as well as uphill, without offering to break into a trot, for a great distance of ground; and, although not *appearing* to go more than at the rate of nine miles in the hour, are really going twelve. This is the result of the perfection of the points to which we have alluded, and can never be looked for in horses of a contrary make, whose shoulders are short and stiff, and their hinder legs straight. Above all things, what is called "fighting action" in a hackney should be avoided; neither ought the fore leg to be thrown out with a dart, as it is always attended with a dwelling, or temporary suspension of the foot, previously to its reaching the ground.

Most horses have some peculiarities about them, if not absolute "tricks," as vicious practices in horses are designated. Starting has already been noticed; but plunging is still more dangerous, as in that case, a horse seldom stops until he have unseated his rider, at least made many attempts to do so, or thrown himself upon the ground. This latter trick often proceeds, not from sheer vice, but from a sense of pain in the horse, from being too tightly girthed; or from the, to him, very unpleasant sensation of a cold saddle, with a weight upon it, being pressed to his back; and having once taken a dislike to it, he is very apt to continue it. Against each of these evils, it is in our power to provide. Against the first, by not girthing the horse tightly, for the doing of which there is no good reason; and against the second, by having the saddle put on an hour before the horse is wanted, in which time it will become warm, and not disagreeable to the skin of his back, which, in some horses, we know to be extremely susceptible. It is upon this principle that the collars are left day and night upon such road coach-horses as are given to "jib" at starting, the consequence of tender shoulders. But there is one failing to which hackneys are subject, not proceeding from vice, but still attended with danger, as it is often the cause of their falling; and we will endeavour to exhibit this failing. We need scarcely insist upon a good mouth, with neck and head in good place, in the best description of road-horse; nevertheless, if he will not suffer his rider to avail himself of those advantages, they are useless to him. Such, however, is the case when a hackney, as he is going along in his fast paces, throws his head backwards, which he has always the power to do, his rider being unable to prevent him. Twofold danger attends this fault. First, when in the act of doing it, he sees not where he places his feet;

---

[1] White says forty-five.

secondly, his rider loses his mouth for the moment, and in that moment he may fall. Independently of this, it gives the rider the idea that the horse is becoming fatigued, and doubtless it is an indication to that effect. Our idea, then, of a *perfect* hackney to carry a gentleman, is this: A well-bred, short-legged, lengthy horse, with *very good legs and feet*, not under fourteen nor above fifteen hands high, that will walk four miles in the hour, trot eleven or twelve, and, if wanted, will go fifteen in that time in a canter or hand-gallop, *without once throwing up his head*, or requiring to be pulled up. We are, of course, supposing him to be in good condition, and in strong work, or it would not be fair to exact so much from him. But it is only in cases of necessity that any horse should be made to perform the latter task; for we are averse to trespassing unnecessarily upon the powers and capabilities of so noble an animal. On the contrary, we recommend every indulgence that can be granted to him on a journey, and especially in hot weather. At all times, indeed, it is our interest to do so; but, in very hot weather, a few sips of soft water, often given, keep off fever, and replenish the loss he sustains by exhaustion from excessive perspiration.

One word more respecting action. We are no advocates for *very fast trotting*. It forces the animal to the very extent of his powers, which, of course, wears him out; it induces his owner either to be constantly displaying these powers in private, or matching him against time in public. Add to this, fast trotting is not a gentlemanlike pace; that is, it has not a gentlemanlike appearance, neither is it agreeable to the rider. This is apparent at first sight, when we follow two horsemen on a road, one on a fast trotter, and the other on a good canterer; although going at the same rate, the cantering horse and his rider are both much more at their ease. With the ancient Romans, indeed, a trotting horse was called a tormentor. Nevertheless, we admit that fast trotting is a proof of action, in excess, but of a peculiar nature, and is, perhaps more than any other, transmitted from sire to son, as the produce of the various Norfolk and American trotters have shewn. The amble is a pace very little known in England, although very general on the Continent, where the act of rising in the stirrups by the horseman, in the trot, is not practised. We wonder, however, that horses are not oftener broken to this pace than they are, for the use of women, or of men unequal to fatigue. Although the amble is not allowed to be a pace in the manège, the walk, trot, and gallop being all, it is said to be the first pace of the horse when a foal, but when he has strength to trot, he quits it. Another peculiarity attends it. A horse, we know, can be put from a trot to a gallop without stopping, but he cannot be forced from an amble to a gallop without a halt.

The Pack-Horse. This description of horse is not now in use. His capabilities were prodigious in carrying weight, but were abused by being trespassed upon. When crossed with the heavy cart-horse, a most useful breed for draught was produced, as also what was called the farmer's hackney, that is, a sturdy animal between the cart-horse and the hackney, useful for all purposes of agriculture, as well as for carrying his owner, and always ready to give help, upon a pinch, either in the plough, the harrow, or the harvest-cart.

The Cob. The word cob is one of new mintage in the sporting world, signifying a powerful, short-legged horse, about fourteen hands high, without any pretensions to blood, but able to carry a great weight, at a certain pace, on the road. He is generally the produce of a light, active cart-mare, and either a thorough-bred or half-bred stallion; and, failing to grow in height, often increases in lateral growth to substance equal to that of the old pack, or miller's horse, of former days. When gifted with action, combined with good shape and appearance, this description of horse is much sought after in London, as also in the country, and often sells for a hundred pounds, to carry heavy elderly gentlemen. The attempt to breed him, however, is a hazardous one, as in case of fault in his action for the saddle, he is not suitable to the coach-horse market, the present rate of travelling requiring more lofty as well as higher bred cattle.

The term *Galloway* now applies to any horse not exceeding fourteen hands in height, although it originated with a breed peculiar to a province of Scotland known by that name. In the early days of English racing, there were several capital thorough-bred galloways in training, at the head of which was the Bald Galloway, sire of Cartouch, and also of the Carlisle Gelding, who, as the Stud-Book informs us, "was remarkable for having supported the fatigue of running as a trial horse in private, and with success in public, till the age of eighteen, at which period, after winning a heat at Sawtry, in Huntingdonshire (1731), he broke his leg, and died." The celebrated Mixbury Galloway, of the middle of last century, was only thirteen hands two inches in height.

Previously to the improved system of coaching, and the cheapness and expedition of that mode of travelling, the well-bred galloway was the favourite hackney of jockies, graziers, horse dealers, and cattle jobbers, and in fact of all light weights who had occasion to travel long distances on the road, in a short space of time; and no description of horse is better adapted to the purpose. Some years since, there was a little entire horse in Devonshire, called Katterfelto, the sire of many most extraordinary galloways, to whose labours on the road, indeed, there appeared scarcely to be any limit.

The Pony. A horse is called a pony when under the height of thirteen hands, four inches to the hand. It is difficult to account for this diminutive breed, unless we believe it to have been imported from countries farther north than Great Britain, which appears probable from the fact of ponies being found in greater abundance in Scotland and Wales than in any other part of the island; the effect, no doubt, of climate. In Ireland they are very rare.

There is no animal that improves in form and character so much as the pony does from the effect of good grooming and high keep. A real Welsh mountain pony, in very good condition, especially if not castrated, is a perfect war-horse in miniature, uniting almost every good property his species possesses. As a proof of one essential quality, we can state upon authority, that the Earl of Oxford had a mare pony, got by the Clive Arabian, her dam by the same horse, out of a Welsh mare pony, which could beat any of his racers four miles at a feather weight. Whether Welsh, Scotch, or Hampshire (New Forest), ponies have properties belonging to them, which should attract the notice of the hippopathologist, among the most prominent of which are the following: They are never lame in the feet, or become roarers. A broken winded pony is a very rare sight, and they live to the extreme of old age, if not unfairly treated. They are also very little susceptible of disease, in comparison with other horses; and as for their powers of endurance, they stagger belief. A rare instance of the latter excellence may be produced, from the well-known fact of the pony, Sir Teddy, only twelve hands high, accompanying the royal mail from London to Exeter, and arriving in that city fifty-nine minutes before it, distance 172 miles, in twenty-three hours and twenty minutes. It may scarcely be necessary to state that he carried no weight, being led between two horses all the way; nevertheless it was a task that we think no full-grown horse would have performed. A correct likeness of this pony was painted by the elder Marshall, of Newmarket. In 1784, a Shetland pony, eleven hands and a half high, carried a rider weighing five stones from Norwich to Yarmouth, and back, forty-four miles, in three hours and forty-five minutes. As a proof, also, of their powers in crossing a country, the fact may be stated of the late Sir Charles Turner riding a pony ten miles in forty-seven minutes, and taking thirty leaps in his course, for a wager of 1000 guineas with the late Duke of Queensberry, then Earl March. During the drawing of the Irish lottery, the expresses from Holyhead to London were chiefly conveyed by ponies, at the rate of nearly twenty miles in the hour.

The only bad use to which the pony is applied, is in what is called the "pony chaise," or phaeton. The carriage itself is dangerous, by reason of its extreme lightness and shortness, by which it is so easily overturned; and the lowness of the driver's seat prevents proper command over the animal drawing it. It is too often the case, also, that "the pony" is a pet, and for that reason pampered in the stable, and not much worked. On the least alarm, then, such as any unusual noise, horses gallopping past him, or, as there have been too many fatal instances, some part of the fore-carriage touching his hocks in descending a hill, away he goes, gallopping and kicking until he has rid himself of his load. The safest way of using ponies in harness, is in pairs, in double harness, with the pole of the carriage raised a little at the futchels, to prevent their kicking over it in their play.

THE CHARGER.

No kind of horse, no animal, indeed, of any sort, makes so prominent a figure in history, sacred or profane, as "the goodly horse of the battle," or war-horse. The description of him by Job is admitted to exceed the powers of human eloquence; "and," as M. Rollin says of it, "every word would bear an explication to display its merits." The *Guardian* (No. 86) has a very ingenious critique upon it; and Bochart devotes seventeen pages to this, and all the other passages in Scripture in which the horse is mentioned. Virgil's representation of him, in his third Georgic, is considered as the nearest approach to that of the sacred writer; and the speech, in the tenth Æneid, of the hero Mezentius to his favourite charger, when on the point of sallying forth to avenge the death of his son, is not exceeded, in the pathetic, by any other passage in the poem. Homer is blamed for his too frequent allusions to the horse; but the history of all wars produces materials for panegyrics on this noble animal. The far-famed Bucephalus is said to have preserved the life of Alexander, by carrying him out of reach of the enemy, although he had received his mortal wound, and dropped down dead immediately on his (Alexander's) alighting from his back. In the battle which was to decide the fate of Persia, on the ground upon which the great Nineveh once stood, the merit of the victory was chiefly ascribed, by the Byzantine historians, not to the military conduct, but to the personal valour of their favourite hero, in which his horse bore his share. "On this memorable day," says the eloquent Gibbon, "Heraclius, on his horse Phallas, surpassed the bravest of his warriors. His lip was pierced with a spear, the steed was wounded in the thigh, but he carried his master safe and victorious through the triple phalanx of the barbarians." How many British soldiers have owed the preservation of their lives to the courage and docility of their horses.

The movement of turning being the most difficult with the horse, by reason of the inflexible nature of his backbone, the one selected for a charger should have great freedom of action, having his hinder legs well bent under his body, so that he may be easily thrown upon his haunches; also much liberty in his shoulders, and pliancy in the muscles of the neck; in which case he will seldom fail in having the proper requisites for his calling. The position of his hinder legs, however, is most particularly insisted upon, because, should they be straight, that is, not inclining inwards from the hock, after the form of the ostrich's leg, he will with great difficulty be made the supple, short-turning, handy animal that he ought to be, to render him perfectly available to his rider, at the head of his regiment, or in the ranks. Perhaps those horses which were destined to mount our ancient nobility, or courteous knights of old, for feats of chivalry, and gained them the palm in that field of romantic honour, were more highly "dressed", as the term is, in the manège, than an officer's charger of these days should be; nevertheless, as Colonel Peters observes, in his Treatise on Equitation (London, 1835), "Although it might spoil a good horse for military purposes, to form him perfectly after the higher manège principles, yet he would be equally unfit for that duty, if he were left in a raw and ignorant state."

Amongst the ancient Greeks, all horses, as well as all men, were strictly examined before they were admitted into the cavalry; and the precedent cannot be too closely followed. It is well known, that in the various campaigns of the last war, several British officers lost their lives, in consequence of being mounted on chargers not equal to their weight over every description of ground. In one particular instance, a colonel of a light dragoon regiment was cut down in retreating, by reason of his handsome, but powerless charger, being unable to gallop with him over a deeply-ploughed field. At the battle of Waterloo, the ground became excessively wet and soft, owing to continued rain; and, in consequence of it, the Duke of Wellington gave a large price to an officer on his staff for a fine, powerful mare, which had been purchased out of an English fox-hunting stud. In fact, the sort of horse best fitted for an officer's charger, is one which possesses most of the essential qualifications, as well as accomplishments, of a hunter, as his rider, when on service, knows not how soon they may be called for. He should, however, be of airy form, with light action, and well-bred, or he will not look in character with the smart costume of his rider; but to his appearance there must not be sacrificed those essential points, substance and strength, which will enable him to struggle through difficulties, in which a weaker, though more highly-bred, animal might sink. But a trifling deviation in form in the charger, from the points insisted upon in the hunter, may be admitted. For example, the shortness of leg, that is, in the cannon or shank bone, is not exactly desirable in the charger, as his action is required to be of a grander and more showy appearance than we wish to see in the hunter. A moderate length of leg, then, is favourable to such action, and gives lightness, as well as gracefulness, to his movements.

We cannot imagine any brute animal more likely to insure the gratitude of man, than the horse which has borne him in safety throughout even a single campaign; and it is not to be wondered at its having been made a subject for rebuke to Cato, that he left his charger in Spain, to avoid the expense of bringing him home; or that it should be recorded in praise of Andromache, that she fed the horses of Hector with her own hand. A case parallel with the first, we would not produce if we could; but without having recourse to history beyond the period of our own time, we may set forth a flattering resemblance to the second. The late Duchess of Wellington, during her Grace's residence at Strathfieldsaye, in Hampshire, seldom omitted, for a day, feeding, with her own hands, the favourite charger of her gallant husband.

The height of a charger should not exceed fifteen hands and a half, horses of that size being more easily set upon their haunches, and also made to turn more readily than taller ones. His colour must depend upon circumstances;

but next to the silver gray, which best displays his trappings, and which, we may presume, was the colour of the celebrated Phallas (the Greeks called a gray horse φαλιος), bay, black, and chestnut, are the best.

THE TROOP-HORSE.

A change for the worse has taken place in this description of horse, in several British light dragoon regiments, the effect of which was apparent in the late war. It originated in a wish to imitate the style and character of the Hussar, without taking into consideration the fact, that that description of cavalry was intended more for out-parties and skirmishing, than for coming in contact with the body of an enemy; and that consequently, the slender sort of horse on which the English light dragoon has of late been mounted, has not been found efficient, under the immense weight he carries when in marching order, or even in battle, which averages at least sixteen stones. The heavy dragoon horse is, indeed, very little more powerful now than that of the light dragoon was, thirty or forty years back.

The horse best calculated for a light dragoon trooper, is something between the modern coach-horse and the hackney; upon short legs, with good bone, and with much substance in the body. His back should be short, and well ribbed up, his barrel round and large, to allow plenty of room for food, as he is often a long time without it; and hardiness of constitution is a very material point in a soldier's horse. When we look at dragoon regiments, however, the heavy horse regiments, in particular, our surprise is excited at the fine appearance the horses make, contrasting it with the price allowed by government for the purchase of them. It is true they are purchased when young, many of those for the household troops, at three years old; and their good keep, upon hard food of the best quality, forces them into shape, and makes them what we see them.

THE COACH-HORSE.

If it cannot be absolutely asserted that the first use of the horse was in harness, it is quite certain that the chariot-horse was held in high estimation in very early times, and is alluded to by poets and historians of all nations and in all languages. Homer says that Diomed, an Asiatic prince, had ten chariots, with a particular sort of horses for each; and he also makes Nestor, at the funeral games of Patroclus, harness the horses for his son with his own hands; and, by his skill in directing him in the race, he wins it. But the Grecian bard goes still further into minutiæ. He even represents Menelaus, on the same occasion, using Œthe, one of the horses of Agamemnon, with one of his own; and Priam is found harnessing his favourite steeds to the car, in which he returns, with the dead body of his father, from Achilles's camp, on the plains of Troy. It would be endless to turn to other writers, to shew the estimation in which the chariot-horse has been held.

In its present acceptation, the term "coach-horse" includes two varieties; namely, the horse that draws the gentleman's carriage, and the one that is employed in those public conveyances, called "stage-coaches." As regards the former animals, we believe a similar alteration has taken place in the form, appearance, and breeding of them, as has been seen in the English hunter, within the last half century. The Flanders mares, so highly esteemed, and seen only in the carriages of families of distinction; the well buckled-up, long-tailed blacks and roans, have all disappeared, and we find, in their stead, the sort of horse nearly approaching to the one which was formerly considered quite well-bred enough for the chase. But the fact is, such is the present rage for rapid travelling, both in private and public carriages, that nothing but well-bred horses have a chance to stand what is called harness-work on our roads. Those used also for "town-work," as the term is, are of a superior description, amongst which hundreds of good hunters might be selected; but such have been the high prices given for them by the dealers, at an age which would not admit of their being tried in the field, they have found their way into harness, and, when once there, they remain in it.

Coach-Horse.

The form, however, of what may be termed a splendid town coach-horse, need not be, by any means, perfect; and were a judge to examine minutely the points of vast numbers of those handsome horses seen in the carriages in London, or other large towns, he would find them very deficient in several points, essential to any purpose but harness, shoulders and hinder legs especially. But it is fortunate for breeders of horses, that it does not require true symmetry and action to form a grand coach-horse. His false points are, for the most part, concealed by his trappings; and if he be any thing near the following form, he will make an excellent appearance in harness. His head is not so material, as the bridle covers so much of it; but his neck should rise well out of his shoulders, as the higher he carries his head the better, provided the form of his neck admits of its being drawn inward by the bearing rein, when only moderately tight, in which case he will be easily acted upon by the driving rein. The back of the coach-horse is a material point, as, without an easy slope behind the withers, his fore-hand will not appear grand, nor will the pad sit well upon him. His hinder quarters should be straight and blood-like; his gaskins well spread; and his tail should be set on, high. His action should not be too short for town-work, but the knee should be thrown well up in the trot, to give him a grand appearance. This peculiar action, the result of strong flexor tendons, suited nearly to this purpose only, is observable in colthood, but is increased afterwards by the horse being thrown more upon his haunches by the bit; and the act of drawing is not unfavourable to it. Light work in harness, indeed, is favourable to all action, that of gallopping excepted.

The county of York may be called the modern Epirus, as in that and Lincolnshire are the greater part of the London coach-horses bred. The most usual cross is between the thorough-bred horse and the Cleveland-bay mare; but the appearance of too many of them incline us to believe, that, losing sight of their own interest, breeders have recourse, oftener than they should, to the half-bred horse, as well as to the half-bred mare. This, added to the rich grass land they are bred upon, accounts for the coarse, ill-placed shoulders and flat, fleshy feet that so many of the London coach-horses exhibit. For road-work, in noblemen and gentlemen's carriages, horses cannot be too nearly full blood, provided they have strength equal to their work. Here, as over a country, "it is the pace that kills;" and as, in considerable velocity, the power of a horse is nearly exhausted in moving his own body, he needs every advantage we can give him.

The colour of the gentleman's coach-horse is, for the most part, bay; but by far the most imposing in harness is the silver-gray, with black mane and tail. This colour was held sacred by the ancients; and Camillus is said to have given great offence to the Romans by being drawn through Rome, in his triumph, by four gray horses, no general having before ventured to do so. Gray coach-horses, however, require the nicest grooming, and the best appointed harness, otherwise all the good effect is lost. The piebald look conspicuous, and commands a high price, as no doubt he always did. Virgil was partial to the piebald, or party-coloured breed, and mounts young Priam upon one of them in the fifth, and Turrus in the ninth, Æneid, both Thracian horses.

Coach-Horse.

The stage coach-horse has undergone a still greater change in the last half century, and particularly the last twenty years. In fact, his physical condition may now be said to be better than that of the man who lives by the sweat of his brow, for he works but one hour in twenty-four, whereas the man works twelve. The coach-horse also lives on the best fare, which cannot be said of the labouring man. As all kinds of horses of a light description find their way into coaches, it is useless to attempt to fix a standard by which they should be measured, as to height, length, width, or strength. But as all horses draw by their weight, and not by the force of their muscles, which could not act against a load for any length of time, the object of the breeder or purchaser of the road coach-horse should be, to have as much power in as small a compass as may be possible, combined with good action. Substance is a *sine qua non* on roads that are heavy or hilly; for, as before observed, it is the weight of the animal which produces the draught, whilst the play and force of its muscles serve to continue it.

There are, however, a few points very necessary to be observed in the purchase of the road coach-horse. As in drawing, the force applied proceeds from the fulcrum formed by the hinder feet, well spread gaskins and thighs form a main excellence. His fore-legs also should be good to make him a safe wheel-horse, nor can he throw his whole weight into his collar, unless he be sound in his feet. But alas, how many are thus deprived of their natural powers, by being worked upon unsound feet, and expected to exert themselves to the utmost.

There is no truth so easily proved, or so painfully felt by the post-master, at least in his pocket, as that, *it is the pace that kills.* A horse at a dead pull, or at the beginning of his pull, is enabled, by the force of his muscles, to throw a certain weight into the collar. If he walk four miles in the hour, some part of that muscular energy must be expended in the act of walking; and, consequently, the power of drawing must be proportionally diminished. If he trot eight miles in the hour, more animal power is expended in the trot, and less remains for the draught; but the draught continues the same, and, to enable him to accomplish his work, he must tax his energies to a degree that is cruel in itself, and that must speedily wear him out.

Let it be supposed, what every horse cannot accomplish, that he shall be able, by fair exertion and without distress, to throw, at a dead pull, a weight into his collar, or exert a force equal to 216 lb.; or, in other words, let him be able to draw a load which requires a force of 216 lb. to move. Let him next walk at the rate of four miles in an hour; what force will he then be able to employ? We have taken away some to assist him in walking, and we have left him only 96 lb., being not half of that which he could exert when he began his pull. He shall quicken his pace to six miles an hour, more energy must be exerted to carry him over this additional ground. How much has he remaining to apply to the weight behind him? 54 lb. only. We will make the six miles an hour ten; for it seems now to be the fashion for the fast coach, and for almost every coach, and every vehicle, to attempt this pace. How stands the account with the poor beast? We have left him a power equal to 32 lb. only to be employed for the purpose of draught.

The load which a horse can draw is about fifteen times greater than the power exerted, supposing the road to be hard and level, and the carriage to run with little friction; and the horse which, at starting, can throw into the collar a weight or force equal to 216 lb., will draw a load of 3200. Let him, however, be urged on at the rate of ten miles in the hour; deduct the power used in swiftness of pace from the sum-total of that which he possesses, and what remains? not a sixth part, not that which is equal to a quarter of a ton, or, if it be a stage-coach, the energy exerted in draught by the four horses will not be equal to a ton.

The coach, and its passengers, and its luggage, weigh more than this, and the whole is still drawn on, and must be so. Whence comes the power? from the overstrained exertion, the injury, the torture, the destruction of the horse. That which is true of the coach-rose, is equally true of every other. Let each reader apply it to his own animal, and act as humanity and interest dictate.

It would be in vain to attempt any standard for road coach-horses. They must be picked up where they can be found, and, if possessed of action, the rest must be left to chance. A good constitution is desirable, for many die in the "seasoning," as it is called, on the road, and a young, green horse cuts a poor figure in a fast coach. Coach-masters are too much given to purchase infirm horses, by which they incur loss, for, if quite sound, it is as much as can be expected that they remain so for any moderate length of time; and we believe the average duration of horses in fast work is not more than four years, if purchased sound. Unsound horses, then, cannot be supposed to last nearly so long, independently of the cruelty of driving them. The most likely horse, however, to stand sound, and do his work well in a fast coach, is one, that, with sufficient strength, and a good set of limbs, has action sufficiently speedy to admit of his keeping time without going at the top of his pace. When this is the case, he runs his stage, from end to end, within himself, and is as good at the last as he was at the first; but when he cannot *command* the pace, he soon becomes distressed, and is weak at the end of his stage. This accounts for sundry accidents having occurred by wheel-horses being unable to hold back a loaded coach down hill, at the end of the stage, although they would have been more than equal to it at the beginning of it. In fact, many coach-horses are very good for eight miles, but very bad for ten, so nicely are their powers measured in harness. Above all things, we recommend good legs and feet in working horses, if they are to be had; and an extra price is well laid out in procuring them. Whether they are strong in their harness, in very fast work, cannot be discovered until they are tried; but well bred ones, having substance, are most likely to prove so.

Dr Johnson, in his Rasselas, makes the Artist of the Happy Valley tell the prince, he had long been of opinion that, instead of the tardy conveyances of ships and chariots, man might use the swifter migration of wings. There appears something prophetic here, when we read of the contemplated transmission, by all-powerful steam, of a man's person from London to Liverpool in two hours, which would be at a rate that the very "wings of the winds" never yet equalled. But surely our coaches now travel sufficiently fast, and we should be sorry to see their speed increased beyond what it now is, in consideration for the sufferings of the horses employed in them. Were they not always *running home* (for each end of the stage is their home), they would not perform their tasks so well as they now perform them; and it is owing to that circumstance that the accidents in fast coaches are not so numerous as might be expected, night work, and many other things being taken into account.

Coach-horses are subject to many accidents, and some diseases nearly peculiar to themselves. Amongst the former is the fracture of a leg, or the coffin-bone of the foot, occasioned generally, it is supposed, by treading on a stone, or any other uneven surface, when the limb is strained in draught. It, however, sometimes happens when the horse is trotting along on very fair ground, and in such cases the accident is rather difficult to account for. In very heavy draught, when the foot is much overcharged with the weight and pressure of the body, a fracture will sometimes take place at the first step the horse takes. Perhaps these accidents may be independent of what is called shape and make, but coach proprietors would do well to purchase their horses with good legs and feet, and then they are less liable to these accidents, and, with good care and good shoeing, may last many years in very quick work.

The diseases peculiar to coach-horses are, the megrims, and the lick. The former attacks the head, and is caused by irregular motion of the fluids within the vessels of the brain, stopping, for a time, all voluntary motion. The horse in consequence staggers and falls, if not immediately pulled up, and that does not always prevent him. This species of vertigo is generally produced by the effect of a hot sun, especially if the horse be running in the face of it, for which reason horses subject to megrims are generally worked at night. In fact, many coach-horses are good horses by night, although they cannot keep their time by day, in the summer, particularly thick-winded horses. Blind horses also do not like sun, but "as healthy as a blind horse in the winter" is a proverb.

The lick can scarcely be called a disease, but it greatly injures the condition and appearance of coach horses. When under its influence, they are almost constantly, when not feeding, licking each other's skins, or else the rack or manger. It proceeds from a heated state of the stomach, from the excitement of high food, and almost daily profuse sweating, and is invariably removed by alterative medicines or physic.

A great mistake is made by too many coach-masters in being *under* instead of *over* horsed for their ground. Instead of keeping five horses to work a certain length of ground, and feeding them very high to perform it, it would answer them better to keep six horses on the same allowance of corn that the five horses are eating. The stock would last longer, and the money they cost be "kept together," as the term is, longer, by such means. Each horse would then rest two days out of six, when they were all fit for work, which would keep him very fresh in condition; and there would always be one spare horse left, in case either of the six wanting physic or rest. It is the almost every-day excitement that breaks down the constitution of coach-horses.

THE GIG-HORSE.

A few years back, a country parson and his wife, or a wealthy old farmer, were the only persons seen in England in two-wheeled carriages, then called Whiskies. They were useful though far from ornamental vehicles, having what is termed "a head" to protect the inmates from weather, and, with a very quiet horse, were considered as nearly equal in security to close four-wheeled carriages. In the character and appellations of these carriages, however, a wonderful alteration has taken place within the last fifty years, and even royalty itself has been seen seated in gigs, cabriolets, Stanhopes, and Tilburies; the two last taking their names from the inventors of their peculiar forms. The build of these two-wheeled carriages has reached the very summit of perfection, not only as regards their firmness but their elegance; and it is scarcely necessary to add, that the horses driven in them, as likewise their harness, have equally altered their character. From two to three hundred guineas (and, in one instance, seven hundred guineas were paid) have been no uncommon prices given for gig and cabriolet horses; and for gentleman's work we might put sixty as the average of the last forty years.

The choice of a gig-horse (for we confine ourselves to that term for the present) must be regulated by local circumstances. If for London streets, his action should be rather lofty or "grand," as the term is, than fast; that is to say, he should step with his knee much elevated, which of course is unfavourable to speed. His appearance also should be of the first order of his species, not under fifteen hands two inches in height; and if of a fancy colour, the more money will he fetch in the market. He must be well bitted, carrying his head high, and very quick in getting into his trot, or "upon his legs," as coachmen say, to enable his driver to make his way in crowded streets. We should also add, that this quickness in his motions should be accompanied by perfectly good temper, and freedom from all vice; in which case he is always worth one hundred guineas, or more, if in the prime of life and sound.

For the country a different sort of gig-horse is required. In drawing a gig on a soft or newly-gravelled road, the resistance is much the same as a continual hill; and therefore a horse with a quick, short step is best calculated for the road, as such action fatigues less than that which we have recommended for London. For all purposes, however, a horse in single harness, to be safe, should be well up before; that is to say, he should go with his fore quarters high up, and not boring on his shoulders. In this case, if he have well-placed shoulders, good legs, and sound feet, free from corns and thrushes; good natural courage to induce him to "run up to his bit," and a good mouth, there will be very little danger of his falling down in a gig; but accidents from vice must depend upon other circumstances. These accidents, however, are often the result not of real vice, or even of ill temper, but of want of knowledge in his owner of putting him properly into his harness, as well as of driving him afterwards.

Innumerable accidents to horses in gigs arise from some part of the harness pinching him, particularly about his withers or back, when he will endeavour to kick himself out of it, to rid himself of the torment. Indeed we have more than once seen a road coach-horse, in regular work, set a-kicking merely from a twisted trace, rubbing edgeways against the outside of his thigh.

We consider mares objectionable in single harness, for reasons which are obvious; and few of them are to be trusted at certain periods of the year, particularly in the case of a rein getting under the tail. When driven, the precaution of the safety rein should not be omitted. We are also of opinion that numerous accidents from gigs would be prevented, if horses intended for them were to be broken in to them, in bridles without winkers, as a great portion of the horses on the Continent are driven. The not knowing what they have behind them is a natural cause of alarm, and would by this means be obviated.

Post-Horse.

THE POST-HORSE.

This description of horse is one of the most useful we have, and is of very ancient date. He is spoken of by Xenophon, in allusion to the posts instituted by the first Cyrus, and as the most expeditious method of travelling by land (*Cyropædia*, l. viii. p. 496, edit. Hutchinson); although, perhaps, he was chiefly made use of to forward public despatches. Augustus was the first to introduce post-houses, and consequently post-horses and post-chaises, amongst the Romans, disposed at convenient distances (Suet. *in vit. Aug.* vi. 49), but these were chiefly for the purpose of political intelligence. Thus, in a letter from Pliny to Trajan, we find him informing the emperor of his having granted a courier a warrant to make use of the public posts, as he wished him to be quickly in possession of some important facts, communicated to him by the King of Sardinia; and he subsequently (Letter cxxi.) apologizes to his royal master for having ventured, on his own responsibility, to grant an order for his wife to be forwarded by post-chaises, on occasion of a domestic affliction. His letter produced a kind answer from the emperor, approving, *in this peculiar instance*, of the use of the warrants which he had entrusted to his care.

Cart-Horse.

A most material and agreeable change has taken place in the character and appearance of this class of horse, who may truly be said to have marched with the times. Up to the end of the last century the post-horse was, except in a few instances, an object of commiseration with travellers. With galled sides and sore shoulders, and scarcely a sound limb, he would not go without the lash or spur, whereas he now comes out of his stable in high condition, and runs his ten miles' stage in an hour, with a carriage of the average weight, and twelve, if required, with a light one. He is also seen to perform either of these tasks without being distressed, unless in immoderately hot weather, when humane persons would check his speed. Montaigne says, "there is a certain general claim of kindness and benevolence which every creature has a right to from man," a sentiment in which we heartily concur; for although man may be considered as the delegate of Heaven over inferior animals, he has no right to go to the very extremity of his authority. It is, however, much to be feared, that a thoughtless indifference to the sufferings of the post-horse is too frequently to be laid to travellers in our own country, who, without any sufficient reason, urge him to a rate of speed which cannot be unattended with suffering.

The form of the post-horse should resemble that of the hunter which is generally ridden in the deep and close hunting countries of Great Britain; that is, with as much blood as can be got, in conjunction with good bone and strength. The riding horse of the pair must have sound legs and feet; but if a little the worse for wear, an old hunter makes an excellent hand-horse, and innkeepers generally avail themselves of the saving occasioned by putting horses of a less price in that place than the one which carries the driver. Notwithstanding this, the average purchase money of a useful pair of post-horses cannot be estimated at less than from L. 40 to L. 60.

THE CART-HORSE.

Errors detected by experience are allowed to be equal to demonstration; but this truism is not admitted by a vast majority of English farmers, who persevere in the use of the heavy black horse for agricultural purposes, for which, solely, he is by no means fitted, from the slowness of his step (independently of his weight), unless very highly fed. As long, however, as the ponderous vehicles made use of in London and elsewhere, for the transmission of heavy goods, are persevered in, this equally ponderous animal may be necessary; but it is certain that lighter horses, in lighter vehicles, would do the business better, that is, more speedily, and at less cost. Notwithstanding the objections to him, the heavy black cart-horse pays well for rearing; for being always saleable at two years old, a certain profit is insured, as, for the first year, the expense of keeping him is trifling. If on a large scale, and promising to be fit for the London market, or the best-conducted road waggons, he commands a price that leaves a handsome surplus to the breeder

The chief desiderata in the cart-horse are substance and action. If possessed of the latter, his shoulders and fore quarters can scarcely be too coarse and heavy; for drawing being an effort of the animal to preserve himself from the tendency which his weight gives him to the centre of gravity when he inclines forward, so the more weighty he is before, and the nearer he approximates this centre, the more advantageously will he apply his powers. Notwithstanding this, we are not advocates of heavy horses for farmer's work, much less on the road. The lighter horse gets over in eight hours what would take the heavy one ten; and the great improvement in the present mode of culture, and the implements used for agricultural purposes, do not require more weight or strength than what the Suffolk, Clydesdale, Cleveland-bay, and other lighter breeds, are masters of. Besides, there are periods of the year when despatch of business is of great moment to the farmer, which he cannot command in those mountains of horse-flesh which we see labouring in most of the finest districts in England, tiring themselves by their own weight.

Travellers on the Continent, occupying land in England, should carry in their eye the form and action of the horses which draw the public carriages, particularly those bred in Picardy, in France. The prevailing colour is *iron* roan, and their nature appears to sympathise with that colour; for, speaking figuratively, they are as hard as iron itself. It is not unusual to find four or five of them drawing those cumbrous diligences, weighing perhaps six or seven tons, a twenty-mile stage, at the rate of six miles an hour, preserving up their condition to the highest pitch; and this with hay and corn very inferior in quality to that grown in England. To keep up the condition of the English black cart-horse, requires him to consume nearly as much as his labour is worth; and unless he lives well, he is only half alive, which his sluggish action denotes. In fact, his chief fault lies in his having too great a body, and too little spirit, consequently he exhausts himself in the mere act of carrying that body. The nimbleness of the smaller kinds of cart-horses to which we have alluded, is owing to their moderate size; and their immense powers in lifting weight (with the Suffolk, Punch, and Clydesdale breeds, in particular) to the same cause, combined with the low position of the shoulder, which occasions weight to be acted upon in a just and horizontal direction. The Welsh cart-horses, especially those in use in the counties of Denbigh, Merionith, and Montgomery, are eminently adapted to all agricultural purposes, combining much strength with a great share of activity; and the general criteria of wide breast, with low shoulders, good carcass, and small head, indicate their being good workers, with hardihood of constitution. Their height is about fifteen hands two inches; and their colour black or brown.

THE IRISH HORSE.

The Irish hackney may be reckoned amongst the indigenæ of his country, a *sui generis* animal, not mixed, as the English hackney is, with the black cart-horse, originally brought from Flanders, of which sort Ireland has none. He is remarkable for the general soundness of his feet, which are stronger in the heels than those of English horses, and he stands his work well, if not too much abused in his youth. Almost all Irish horses coming under this description have been broken in to the plough and the car, so they, for the most part, go in harness; but the worst fault they have is not having been properly broken in, and bitted, which is the cause of many of them being restive.

The Irish hunter is a very different animal from what he was half a century back. He was always celebrated for leaping, but until lately the want of breeding rendered him nearly useless as a hunter, in the countries which require speed, as well as the accomplishment of leaping. At the present time great numbers of excellent well-bred Irish hunters are annually imported into England, and being found to answer well, fetch good prices. This is the result of horse-breeders in Ireland seeing the necessity of putting their hunting mares to thorough-bred stallions, and not, as before, to the slow, *great-jumping* hunter, no matter how low his breed. The improved cross, being again put to the thorough-bred stallion, of course has produced a still better kind of animal, and thus are Irish hunters "progressing" towards perfection.

The method of leaping of the native Irish horse is peculiarly suited to some of our English counties, Cheshire and Lancashire, for example, and likewise to those inclosed with walls both in England and Scotland. To use an expressive Irish phrase, "they have always a leg to spare," implying that they have a ready use of their hinder legs; which is the fact, in tipping or touching walls or banks, with one or both, which gives them a fresh fulcrum, from which they can extend their leap, in case of their finding an unforeseen difficulty or obstacle on the landing side. In the wall counties of Ireland, indeed, the horses are taught to alight on their hinder legs upon the summit of the wall, after the manner of the dog when he leaps a gate, which, if the wall be broad and firm, adds to the facility of the exertion, as also to the safety of the rider. Irish hunters are generally good brook jumpers, being educated, indeed bred, amongst drains; but field gates, or stiles, being of rare occurrence in the pastoral districts of Ireland, they are not to be relied upon as timber leapers, until they have been initiated to that description of fence.

Persons who have had experience in Irish hunters have found them very shy of having a whip, with a thong to it, made use of by the rider, either for the purpose of smacking it, or to strike an unruly hound. This we fear proceeds from unnecessary severity in the exercise of the whip in breaking, but which would be obviated if breeders were aware of the inconvenience it occasions to servants, who are called upon to ride Irish horses with hounds, in the capacity of huntsmen or whippers-in. We have seen a few of these horses nearly useless from this cause, as servants' horses; although well suited in every other respect, to this peculiar purpose, from their style of fencing and hardiness.

The Irish race-horse was formerly far behind the English, neither is it probable that he will ever be his equal, from circumstances unnecessary to detail. Some horses, however, coming under the denomination of good runners, have been imported from Ireland within the last twenty years; for which we are principally indebted to Lords Sligo and Rossmore, and to the late Mr Bowes Daly, who was esteemed the best judge of breeding racers that Ireland ever could boast of. It must, however, be admitted, that horses bred and trained in one country, and running in another, meet their rivals under disadvantageous circumstances.

THE SCOTCH HORSE.

Like all cold countries, Scotland is unfavourable to breeding the race-horse in his best form; and the only prospect of rearing him to any thing approaching perfection, is to shelter him with unusual care from the weather, when either cold or wet, and to force him with the highest keep. Scottish-bred hunters, however, are esteemed in the hunting world as a stout, hardy race, and they, like the Irish, are now well enough bred to live with hounds at the present speedy rate at which those animals run, according to the fashion of the present day. Of the native Highland pony, it is unnecessary to say much, its merits being so well known; and the Scotch cart-horses are decidedly the best in Great Britain. The peculiar variety known as Clydesdale horses, stand first in repute. Of the origin of this race, various accounts have been given, but none of them so clear or so well authenticated, as to merit much notice. They acquired their appellation, not because they are peculiar to Clydesdale, as the same description of horses are bred in the other western counties of Scotland, and over all that tract which lies between the Clyde and the Forth, but because the principal markets at which they are sold, namely, Lanark, Carnwath, Rutherglen, and Glasgow, are situated in that district, where they are also preserved in a state of greater purity than in most other parts. They are rather larger than the Suffolk-punch, and the neck is somewhat longer; their colour is black, brown, or grey; all the essential points for heavy draught are very conspicuously developed; and they are extremely docile withal, and excellent at what is called a dead pull. Some magnificent specimens of this breed are to be seen in the streets of Glasgow, in the service of the merchants and carriers; and a beautiful plate of an entire one forms one of the illustrations of the article AGRICULTURE in the present Work (Plate XIII.) We have reason to believe, that, if tried by a dynamometer, the Clydesdale horse would exceed any other of his inches and weight in his powers of draught; and his quick step adds much to his value.

Treatment of Horses.

GENERAL TREATMENT OF HORSES.

Humanity and mercy are esteemed the choicest characteristics of man; and there is hardly a greater instance of ill-nature, or a more certain token of a cruel disposition, than the abuse of dumb animals, especially of those who contribute to our convenience and pleasures. Judge Hale beautifully expresses himself on this subject in his Contemplations: "There is a degree of justice," says he, "due from man to the creatures, as from man to man; and an excessive use of the creatures' labour, is an injustice for which he must account. I have therefore always esteemed it a part of my duty to be merciful to my beasts." But we might as well expect mercy from the hyæna, as compassion for the sufferings of horses in the possession of a certain portion of the community, who purchase them when nearly worn out, and work them till nature sinks. We know of no remedy for this; but it is pleasing to reflect, that, in the better classes of society, so noble, generous, and useful an animal as the horse, is now freed from many evils to which he was formerly subjected. The short-docking of the cart-horse, the effect of prejudice and ignorance, it being supposed to add strength to his back, is very generally discontinued, and he is allowed the use of a full tail, the only natural defence against the torment of flies in the summer. Those barbarous operations, nicking the tail, and cropping the ears of pleasure horses, are very seldom had recourse to; neither is firing the limbs nearly so frequent a remedy as it was, veterinary science having substituted other equally efficacious, but less painful means. And, though last, not least, the improved condition, and the effect of better stable management, of all horses employed in fast work, whether on the race-course, in the field, or on the road, has very considerably lessened their sufferings. On this subject we offer the following remarks:—

Condition or Stable Management of the Horse.

Nothing has more largely contributed towards the celebrity of the horses of Great Britain, than the superior management of them in the stable, or what is termed their "condition." Every species of horse has experienced the benefit of it, and we have reason to believe it has attained perfection, under the improved system adapted to each variety of the animal. The training of the race-horse is brought to such a nicety, that his running can be calculated nearly to a certainty by his work, that is, by the number of sweats and gallops he has had before his race; and the stage-coach and post-horse now come forth from their stalls in all the pride of health and spirits, instead of being the pitiable objects they were not fifty years back. Not only the hackney, but the agricultural horse, has partaken of this advantageous addition to natural powers, and which, if not unnecessarily trespassed upon, very considerably diminishes the severity of his daily labour. But the greatest change for the better has been effected in the physical condition of the hunter, who now appears at the cover side in the vigorous state of the race-horse; in a state, in fact, in which he ought to appear, inasmuch as he is called upon to go at a racing pace and yet, if fairly ridden throughout the chase, he is by thi means rendered nearly superior to fatigue. How all this ha

Treatment of Horses.

been accomplished, we will endeavour to shew; and at the same time to make it apparent, that although Nature never presents us with animals in what we call condition (a state altogether artificial), yet she is ever ready and desirous to meet the demands of Art, when scientifically and judiciously made upon her.

The improvement in training the race-horse has been the result of two distinct causes, each equally likely to produce the desired effect. First, practical experience, an excellent schoolmaster in such matters; and, secondly, both breeders and trainers of this animal now look into books, not only reading them, but reflecting upon what they read. Having been told, on indisputable authority, that the highly rarefied air and arid soil of Arabia produce muscular power and firmly condensed bone in the horse, not to be found elsewhere, and that the antelope, the fleetest animal in the world, is fleeter there than in any other part of the globe, they have naturally been led to the conclusion, that the opposite agents of humid atmosphere and succulent food have a directly opposite effect; that by increasing flesh and humours, they tend in proportion to diminish muscular firmness, solidity of bone, and, consequently, elasticity of action, the main-spring of both speed and endurance; in short, to alter, if not to destroy, all those points which are so peculiarly characteristic of the animal in which they themselves are interested. They have at length found out, that the race-horse should have not an ounce of unnecessary bulk in his frame; on the contrary, that he should have as much power as can possibly be produced in a given space; and that all this can only be effected here by something approaching to the means by which it is effected elsewhere. A knowledge of these facts, then, has produced a substitute for the natural advantages of the horse of the Desert, in warm sheds, very small and dry paddocks, and hard, dry food, for our racing colts, instead of large paddocks, plentifully clothed with grass, often of the coarsest description, imperfectly formed sheds, and not more than half the corn eaten by them at present. As we have already observed, a racing-colt may now be said to be in training, if not from the day on which he is foaled, from that on which he is weaned; for his condition, at least the foundation of it, is from that period in progress. Again, the early period of his going into work, compared with what it formerly was, but now become so general, has not been without its effect. It has called forth additional exercise of the trainer's professional skill; for it may easily be imagined, that, bringing very young horses to the post, in the perfect state of condition, and full development of muscular power, in which we now-a-days see them at every race-meeting in our island, is a very difficult task, and that it is a still more difficult one to preserve them in that state, even for a few days. Both constitution and temper being to be consulted, the very refinement of the art is called for; in fact, the trainer must act upon principle, and very cautiously too, in his efforts to forestal nature. Inasmuch, however, as muscular action produces muscular strength, the racer of the present day, reared as he is reared, and consequently in a more condensed form, does not, with few exceptions, require the very severe work which it was formerly necessary to give him, to increase his muscular powers, as well as to rid him of the bulk of flesh and humours he acquired in his colthood, under the old system of rearing him. A sight of our two-year olds at the starting-post, is the best demonstration of what is here stated. They exhibit a development of muscle in their forced and early maturity almost equal to that of the adult horse, and carry eight stones and upwards, at a racing pace; a weight unheard of upon so young an animal in former times. How far, however, this forced maturity and its consequences, namely, severe work, and the excitement of high keep, at so tender an age, are favourable to him or to his produce in after life, is another question; but the use of a system should never be estimated by the abuse of it. If our race-horses are not, and we believe they are not, so stout in their running as formerly, that is to say, twenty years back, the cause may fairly be traced to the great value of produce stakes and others, which bring them to the post at so early an age; so much so, that, in the language of the Turf, a four-year-old colt of the present day is called "*the old horse.*"

But a still more material alteration for the better has taken place within the last few years in the stable management and condition of the British hunter, arising principally from a different treatment of him in the non-hunting months. It had, from time immemorial, been the usual remark of the sportsman, on his hunters being turned out of their stable in the spring, for the *supposed* necessary advantage of the "summer's run at grass," that it was to be lamented that the hunting season was concluded, as the condition of his stud was so perfect. The fact was, that until then, or nearly till then, they had not been in condition at all; and, how strange soever it may appear to any one reflecting upon the subject, by the act of turning them to grass for this "summer's run," he was about to undo all that his groom and himself had been doing during the nine preceding months, namely, to destroy the perfect state of condition which he was at that time lamenting over. Still more strange, however, is the fact, that although the evils of this out-of-door system for three months in the year, to an animal who lived the other nine in warm stables and well clothed, were hinted at by Mr Beckford, in his celebrated *Letters upon Hunting*, and abandoned by a few of our first-rate sportsmen of, and subsequent to, his day, and particularly about the commencement of the present century, by the example of the Earl of Sefton, when he was owner of the Quorndon hounds, in Leicestershire, still the ruinous system of the three, and generally four months' run at grass (viz. from 1st of May to the 12th or 20th of August) continued to be practised, until these evils were exposed in all their appalling deformity, and the advantages of an opposite system made manifest, in a series of letters in the *Old Sporting Magazine*, under the signature of "Nimrod," which have since been published in a separate form, and very widely circulated. We may also add, that the effect of this exposure has been nearly a general abandonment of the grazing system in the studs of all men who mean to ride near hounds.

Previously to our enumerating the real advantages of the modern system of "summering the hunter," we will state the imaginary ones of the old one, and which, as may be supposed, are still held to be such, by those who reluctantly acquiesce in any kind of reform. First, the purging by spring grass is insisted upon. Secondly, a relaxation of the muscles, and what is called a letting down of the whole system to its natural state. Thirdly, the benefit the feet receive from the dews of the evening, and coming in contact with the cool earth. Fourthly, the saving of expenses. Fifthly, a kind feeling towards the animal, who, they say, is entitled to his liberty for a certain period of the year, also to the free enjoyment of his natural state. And, lastly, the absolute necessity of rest to the limbs, after the labours of the preceding season. We will now make our own comment on each of these presumed facts.

And, first, we admit there is a laxative, and therefore a cooling, property in early spring grass, but as a purgative it is insufficient, which is admitted by the fact of its having been generally considered necessary to give two dozes of physic to hunters previously to their being turned abroad for the summer (thus administering the antidote, as it were, before the poison), and to physic them immediately when taken up. Here, then, is at once an answer to the first objection to the improved system of in-door treatment in the summer; even supposing that spring grass could not be given to a horse in a loose box, whereas it is evident that it can.

Secondly, the entire letting down of the system, by a

Treatment of Horses.

sudden change of food from that which is highly invigorating to that which is only succulent and relaxing, is neither called for, nor can it be wholesome. It is never had recourse to with the race-horse during his period of inactivity, and why should it be with the hunter? We would ask the owner of a horse so treated, how he thinks it would agree with his own constitution and his *digestion*, to be suddenly taken from beef and port-wine to a purely vegetable diet; and the analogy holds good.[1]

Thirdly, a great mistake has prevailed on this point, the preservation of the feet. A certain degree of moisture is beneficial to the foot of the horse, a continued exposure to wet most injurious to it, as the certain cause of thrushes, and in time total destruction of the frogs. Thus, history informs us that the horses in Hannibal's army were rendered unserviceable by travelling many days in succession in very wet ground. But we have better authority here than that of Livy, because it applies to horses which wore shoes, whereas Hannibal's wore none. Mr Goodwin senior, late veterinary surgeon to his Majesty George IV., in his work on the Diseases of the Feet (p. 209, 1st edit.), has the following passage, in allusion to the evils of having the feet of horses saturated, as they must be during a summer, with wet at one time, and then suddenly exposed to a hot sun and a drying wind at another. "I have invariably observed," says Mr Goodwin, "where horses are turned out to grass during the dry and hot summer months, that on bringing them up to be put into stable condition, their feet are in a much worse state than they were when they went out, dried up, and so hard and brittle, that, on the application of a tool to bring them into a form to receive a shoe, the horn breaks like a piece of glass, and all the naturally tough and elastic property is lost, so that it requires some months to remove the bad effects. If it is necessary that a horse should be put out of work during the hot and dry weather, I prefer a large box or shed, and soiling with green food; by which means two objects are gained, viz. all the *injurious* effects of a drying wind or a meridian sun on the hoof are avoided, which create such an excessive evaporation of the natural moisture absorbed into the horn from within, that it not only becomes dry, hard, and brittle, but the whole horny box tightens on the sensible parts, and frequently produces great mischief. But in a loose place, moisture may be applied in any desirable way." In addition to the above, Mr Goodwin says, "Horses at grass are much inclined to thrushes;" which renders it unnecessary for us to say more on this subject at present, although we shall by-and-bye offer the result of our own experience in the treatment of horses' feet in the summer.

Fourthly, a saving in expense. This is an objection too trifling to be admitted in opposition to any real advantages. It was calculated by Nimrod,[2] allowing only four shillings per week to have been the charge for each horse, supposing him to have been summered at grass, that the extra expense of his six hunters summered after his system, which we shall further explain, amounted to only L. 13, 18s. The mere chance in favour of exemption from accidents to which horses abroad are liable, is worth more than this inconsiderable sum to the man who keeps six hunters in his stable; but twice its amount would be realized in the sale of any of the six, if offered at the hammer in November, beyond the sum he would have produced had he been summered solely in the fields.

Fifthly, we would go any length in advocating the extreme of kind treatment to so noble an animal as the horse; but experience has taught us, that neither the open field, nor the shade, is a bed of roses, in the summer months, to the well-bred, and naturally thin-skinned hunter; for the œstrum, or blood-sucker, pursues him in each; and the desperate attempts he often makes to avoid them, shews the horror he has of their attacks. But, unluckily for the advocates of this system, one of the greatest evils of the out-of-door system here stares us in the face. If the horse cannot get away from this host of tormentors, his only remedy against them is, galloping from one end of his pasture to the other, or else stamping with his feet against the hard ground, and often against the roots of trees, to scare them from one part of his body, only to settle upon another. The injury to both feet and legs from a daily succession of these operations, may be left to the imagination of the reader; but against the charge of cruelty, we quote the following remark from *Nimrod's Letters* (p. 268, first edition): "In the very hot weather," (he is speaking of the summer of 1825, which was remarkable for the intenseness of its heat), "I made a few observations, which are not irrelevant to my present purpose, particularly as to the charge of cruelty in keeping hunters in the house, in the summer. On the 29th of July, one of the hottest days, the thermometer was one degree higher, at two o'clock at noon, in my two four-stall stables, in each of which three horses had stood for sixteen days and nights, than it was in the entrance-hall of my house, which is twenty-three feet high, and contains three large windows and six doors, and the aspect due east. Now, will any one tell me, that the most tender animal could be injured by breathing such an atmosphere as this? But all is not yet told. I removed the thermometer on the same day, and at the same hour, into the shade, and there it was *four degrees higher than in my two four-stall stables.* Here, then, the objection to horses standing 'sweating in the stables in the summer time,' returns to its real insignificance."

Lastly, upon the subject of rest, and the means of procuring the advantages of it to the hunter by a summer's run in the fields, we cannot do better than quote from the same author. "When discussing the subject," says he, (p. 262), "of summering hunters with a friend, who is an advocate for the grazing system, he made use of the following expression: 'I dare say it may be all very well to keep them in the house in the summer, but then they have not the benefit of *the rest* which they get when at grass.' I could not help smiling at this strange perversion of facts; and ventured to ask him, Whether, if he were examined in natural philosophy, and asked, *what is rest*, he would answer, *motion?* and that would not be a whit less

---

[1] In No. 59, vol. v. p. 645, of the *Veterinarian*, we find the Editor coinciding with Nimrod on this point, in his second review of his Letters on Condition. "These pithy and valuable extracts," says he, "at the same time that they serve to expose our author's views in regard to summering the hunter, demonstrate a sagacity and experience on the subject, no less worthy of the admiration of the professional man, than of the sportsman himself. The leading consideration in summering the hunter is to maintain his condition, or rather, we should say, to guard against his losing that which we know, both by education as medical men, and experience as sportsmen, once lost, will require much time and pains to be re-acquired. Change of food is necessarily productive, in the animal constitution, of alteration of structure; though parts cannot be said to change their nature under their influence, yet they do become greatly altered both in texture and in tone."

Treatment of Horses.

absurd. If rest be desirable, as we know it is, for a hunter's legs, after the labours of a winter, surely he must obtain it more effectually in a small confined place, than when suffered to run over a large tract of land, and to stamp the ground with his feet for so many hours each day." Neither does the labour to the legs end here. All persons who have ridden horses, whose growth has been forced in their bodies, as that of most hunters has been, must have perceived that, when letting them drink in shallow water, their fore-legs totter under them, in the attempt to reach the water with their mouth. Such is the case with the hunter, at least with the properly formed one, when in the act of grazing (for the horse prefers a short bite); and the tremour in his legs shews the stress that is laid upon them, to enable him to reach his food. In fact, many horses (and we could name some well known hunters) cannot reach the ground at all with their mouths, unless it be by the painful position of placing one fore-foot close to their mouth, and the other even with the hinder legs; and consequently their owners have not been able to turn them out, had they been inclined to do so.

It is now our turn to be heard on this important subject to all owners of hunters; and we proceed to state, that the principal objection to summering a horse abroad, consists in the danger we expose him to by the violent change from a stable at the temperature of 63° (the common one of hunting stables), and the addition of warm clothing, to a bed upon the cold ground on a wet night; or, which often happens in the month of May, to the influence of sharp frost; all this, also, when the animal has scarcely any coat on his back to provide against the effects of bad weather; and with a skin highly porous, from long continued friction in the stable. As well might we expect to find animals and plants that can sustain the heat of the torrid, and the cold of the frigid zone, as horses to bear those extremes with impunity! On the contrary, it is the confirmed opinion of most veterinary surgeons, that more hunters have been ruined by becoming roarers, broken-winded, or blind, from this cause, than from any other to which they are subjected; and they are backed in their opinion by reason. For it is not necessary that the newly-turned-out hunter should be exposed to either a wet or a frosty night, to produce disordered functions; the common exhalations from the ground in the evening, are sufficient to produce them, by a sudden constriction of the pores, opened as they have been by the effect of a hot sun during the day. "Heat and cold, moisture and dryness," says Mr Percival, veterinary surgeon to the First Life Guards, and author of the *Anatomy of the Horse*, in his last work on the Horse (p. 64), when treating on the theory of inflammation, "all in their turn become excitants of inflammation; their mischievous agency residing more in the vicissitudes from one state to its opposite, than in any obnoxiousness in our climate, from their excess or continuance. They may operate either directly as excitants, or indirectly, simply as predisposing causes." Few veterinarians, indeed, as Mr Percival expresses himself, now-a-days, feel inclined to deny the uncongeniality of cold and wet, to the constitutions of horses, or to maintain, that they do not very often, in such situations, contract the foundations for disease, which, at some future time, is apt to break out, and prove fatal to them. Nor are the remarks of this scientific practitioner and most perspicuous writer, less to our purpose, when speaking of the horse that is turned out of his stable in the winter. "Take a horse," says he, in his chapter on 'Hide-bound,' (p. 296), "fat and sleek in condition, out of a warm stable, where he has been well clothed and fed, turn him, during the cold and wet of winter into a straw-yard, and go and look at him three months afterwards, and you will hardly recognise your own horse. You will find him with a long, shaggy, staring coat; a belly double the size it was when in condition; and a skin sticking close and fast to his ribs, which may now be readily counted with the hand, if not with the eye." But here the analogy between the horse turned out to grass in the summer, and the horse sent to a straw-yard in the winter, ceases. The latter loses flesh, and becomes hide-bound, both of which will find a remedy in a return to more generous food in the stable, with the assistance of alterative medicine; and he will speedily resume his condition. But it will not be so with the grass-fed hunter. He has accumulated a load of soft, unhealthy flesh, which must be got rid of at the expense of his legs and feet; or, in the language of grooms, "it must be exchanged for better flesh, the produce of hay and corn." By feeding *ad libitum*, however, he has so plethorized his system, and trespassed upon his digestive organs, that this is become not merely a work of labour and time, but one of no small risk to the general soundness of his constitution. Nor is even this the extent of the mischief. Under the most favourable circumstances, it is not in the power of a groom, how good soever he may be, to bring the grass-fed hunter into the field, fit to be ridden, with hounds, until the hunting season is half expired. For proof of this assertion, we need only go to the race-horse, who cannot be made fit to run under, at least, six months' preparation, although he has not been at grass since he was six months old. Nature will not be put out of her course by violence; and horses can only be got into good condition by degrees, by long continued slow work at first, increasing in pace as their condition increases; and it has been the attempt to get the grass-fed hunter into something approaching to condition, by hurrying him in his work, under a load of flesh, and with his muscles in a relaxed state, that has ruined thousands of good horses, by the injury done to their legs especially; and will ruin thousands more, if persevered in. The change of food, again, has been the cause of more broken-winded horses than any thing else that can be named. "It must dispose," says Mr Percival, "from its being the chief cause of plethora, to general diathesis of the system; and so far it contributes to the production of pneumonia, or any other inflammatory affection." To this we may add blindness, the natural consequence of the dependent posture of the head when feeding, in an animal in the plethoric state that a previously highly-fed hunter must fall into, after being some weeks at grass; and likewise of constant irritation from flies and sun. Neither should the following remark of Mr Percival's be forgotten by gentlemen who turn out their hunters during a wet summer. "Cold," says he, "abstractedly from wet, even although it be alternated with heat, is not found to be near so prejudicial as when moisture is present too; hence we are in the habit of viewing frosty weather as a season of health among horses; and hence it is, that the spring and autumnal months are the most unhealthy, the weather being then moist and variable, and the wind generally in a cold quarter." Again, "Two undomesticated horses," says he, "out of three, under five years old, that are taken from cold situations, and kept in warm stables, will receive catarrh. But even domesticated horses that are advanced in years, and that have been accustomed to such changes, do not always escape, unless some precautionary measures be taken; for hunters taken up from grass in August, unless due attention be paid to the temperature of the stable, are often the subjects of catarrhal attacks."

Perhaps the summer of 1835 may be produced in proof of the danger of subjecting stabled horses to atmospherical changes. In the first week of June, 78, 80, 82, and 84 degrees of heat were marked by the thermometer. On the 13th, the maximum of heat was 15 degrees less than that of the preceding day; and on the 23d, the thermometer fell to 47 degrees, succeeded by four days' rain, with wind veering to south-east, back to west, then to north and north-east, at times furiously high!

We must be allowed two more remarks on the evils of the out-of-door system. Amongst the physical changes which the body is capable of receiving, none is so visibly effected as in the diminished, or increased, size of the belly; and the latter alternation of form is speedily effected by a horse eating grass, and nothing but grass. When a man goes into training for a match against time, or a prize-fight, the first act of his trainer is, to reduce the size of his belly; for, until that is done, his respiration is not free enough to enable him to make such bodily exertions as are essential to augment his natural vigour, and put him into the best possible condition; and this exactly applies to the grass-fed hunter taken up in August. He has exchanged an active untiring frame, for a bloated and breathless carcass; and nothing can be done with him until, by purging and *severe work, when he is not in a fit state to endure it with impunity,* the nature of his frame is altered from weakness to vigorous health. But this must be the work of time, for, although Nature will admit of improvement, she will not allow herself to be hurried by the unreasonable innovations of man.

Our next remarks relate to bodily infirmities and local diseases, to which the horse, by the severity of his labours, is always more or less subject. Several of these, such as splents, spavins, curbs, and ring-bones, are easily checked, if discovered in their incipient state; but when, by being undiscovered for only a short time, a certain progress is made in them, the cure is far from certain, at all events, more difficult. Now, under the old system of the summer's run abroad, this was most frequently the case. Horses, when taken up, were found to have thrown out those excrescences unperceived, which, as soon as they began to work, caused lameness and disappointment; whereas, under the improved system of summering the hunter, they could not have escaped the constant inspection of the groom, and an immediate check would have been given to them. The short-cough, vulgarly and stupidly called a "grass cough," also too often swelled the catalogue of disasters; and, in six cases out of ten, ended in broken wind or roaring. But it may not here be amiss to address ourselves to owners of hunters, who may adopt either one system or the other of treating them in the summer months; we mean, as regards their legs, the treatment of which now forms a conspicuous feature in the science of the stable, particularly the racing stable. Many valuable animals are ruined in consequence of their owners and their grooms not knowing, perhaps not wishing to know, when their legs are going amiss, and consequently stopping them in their work, before the evil gets a-head. It is irksome, no doubt, to give up the use of a hunter, especially if a favourite one, and in blooming condition; but it is only by such prudent conduct, that we can expect a lengthened enjoyment of his services. It is a lamentable fact that, generally speaking, good-constitutioned horses would wear out two sets of legs and feet, which shews the urgent necessity of taking care of them.

We now take our leave of the old, and, we may add, ruinous system of treating hunters in the summer, and proceed to state how, in our opinion (the result of much experience) they ought to be treated in the non-hunting months; as also to offer a few directions for the management of them when in work. To begin, we are far from averse to resting the hunter in the summer, although we cannot shut our eyes to the fact of horses working hard for a great many years in succession, without experiencing what is here meant by "*rest*," (namely, not having a saddle on their backs for three or four months), and remaining sound and healthy to the end of a long life. Our great object is, to give the hunter fair play, by preserving, instead of destroying, his condition at the same time that we rest him; and in this we think, that, by preventing exhaustion in his work when he returns to it, we offer him much more than an equivalent for the fancied enjoyment of his "snuffing the air in his native liberty," and "making his bed on the cool ground," so stoutly insisted upon by many of the old school, who will not march with the times, and who cannot divest themselves of prejudices, how dear soever they may cost them.

The period of "turning *up*," not "*out*," hunters towards the close of the season should depend on circumstances. Those whose legs may be doubtful, should be the first thrown out of work; and after them old ones, who, how well soever they may go over a country when it is soft, are in danger of breaking down when it becomes hard, as it always does in March, particularly in ploughed countries.

The first act of a groom, when his horses have done their work for the season, is to give them two doses of mild physic, which, by their effect on their legs, will greatly assist him in discovering the amount, if any, of the injury that may have been done to them. Should anything serious exhibit itself, we recommend him (unless he be a first-rate professor of his art) to avail himself of the advice of a veterinary surgeon, as to the steps proper to be taken; and the sooner those steps are taken, the better will it be for his horses. The barbarous, the senseless, practice of blistering, generally the two fore-legs, and often the hinder ones also, previously to turning out, under the old system, is now, we are glad to say, abandoned, not only on account of its inutility, but, by the spread of veterinary science, sportsmen have found out that the application of blisters to healthy legs is injurious. The merely irritating the surface of the skin cannot be productive of advantage; on the contrary, it often rouses the sleeping lion, which it is afterwards difficult to pacify. As counteractors of internal inflammation, or as counter-irritants, as they are called, blisters are highly useful; likewise to all bony excrescences, such as splents, spavins, or ring-bones, when in an incipient state; but, in order to render them efficacious, they should be repeated till healthy pus is obtained. If judiciously applied in strains, they are also not unserviceable, as they help to unload the vessels near the affected part. Supposing, then, no serious mischief has been done to the legs of a hunter during the season, we thus proceed in our course of treatment of him:—

Previously to stripping him of his clothes, he should go through his second dose of physic, and be treated exactly as if he were in work for at least a fortnight afterwards, with the exception of his having only walking exercise, a diminished allowance of corn, and the wisp, without the brush, applied to his body. We now arrive at a point on which there is some difference of opinion, at all events, one which must be left to the option of the owner; namely, whether, as is the practice in the stables of some of our first-rate sportsmen, the hunter is to be kept in gentle work throughout the summer, or to be thrown entirely aside for a certain number of weeks, varying from nine to twelve? We will, however, state the best method of proceeding under each of these systems.

The horse kept in work (we should rather have said exercise) during the summer, should be exercised very early in the morning on soft, but not wet ground (a low meadow, or rather a marshy common, for example), that his feet may have the advantage of moisture, and also that he may not be tormented by flies, or exposed to a hot sun. Two hours will be sufficient, the pace to be varied alternately from the walk to the jog-trot. It is desirable that a horse thus treated should not be tied up in a stall, but have the enjoyment of a large loose-house. Of course, attention should be paid to his feet, removing his shoes every third or fourth week; and they should be stopped with wet tow every second night. To those who object to this in-door treatment of the hunter on the score of danger to his feet, we can only say, from our own experience, that their fears are groundless; and we also refer them to the first cavalry barrack they pass by, or even to the stables of our innkeepers on the road, in which they will find feet in the highest state of preservation, that have been subject to in-door treatment for many years. We prefer damp tow to any other sort of stopping for horses' feet, because, exclusive of the moisture, it affords a uniform pressure to the frog and outer sole of the foot, which is favourable to their healthy state. Indeed, to some of the finely-formed, open feet which we see on first-rate hunters, the soles of which are apt to be thin, this pressure is most advantageous in preventing a disposition in them to become flat or convex, instead of moderately concave; and for this purpose was the "horse-pad," or "elastic stopping," invented by Mr Cherry, veterinary surgeon of London, which may be preferable to the tow, but not always at hand. When the latter is used, it should be forced into the foot with all the strength of a man's fingers or thumb.

The food of hunters thus summered should be regulated by circumstances. Good flesh, we know, is strength; but that which is generated in comparative idleness only contributes to weakness. Our object, then, should be to prevent a horse, treated in the manner we now allude to, from throwing up much flesh, and we must therefore feed accordingly, and also study constitution. At all events, three small feeds of oats (we do not feel ourselves justified in recommending beans, although we know some sportsmen give them; except in very peculiar cases, such as extreme delicacy of constitution, a disposition to scour, or throw off food) per day are sufficient for any horse, with the addition of a large, sloppy, bran mash twice a-week. As to green food, we recommend that with caution. We approve of its being given occasionally for three or four days in succession, merely as soiling, to attenuate the blood, not to produce flesh; and this repeated now and then at intervals, whilst the green meat (be it what it may) is young, but by no means afterwards. Many grooms mix hay with green food, which, after the first two or three times of giving it, we think a judicious plan. But, be it observed, for reasons we have already given, we object to a hunter acquiring a load of flesh in the summer, the produce of succulent food. A moderate use of alteratives is beneficial throughout the summer to horses which live well, but do not work, as, by their mild and gradual impression, a healthy action of the bowels is kept up, as well as insensible perspiration increased.

The horse *not kept in work* should be thus treated in the summer: He should run loose in the bay of a barn, or any large covered place where he gets exercise, and breathes fresh air, without exposure to the sun. His physic, food, &c. should be as before directed; but as he is now unshod, and consequently cannot have his hoofs filled with any thing which can impart moisture to them, he should be made to stand two hours every day, under cover, in wetted clay. Unless after firing, or severe blistering, when the sedative powers of cold air are efficacious in checking local inflammation, we prefer the hunter being housed throughout the night, to his lying out even in a paddock, as he is less liable to disease and accidents; but we admit that the danger of exposure to night air is greatly diminished by his having been kept cool throughout the day, by which he is less susceptible of atmospheric influence, or the alternation from warmth to cold, than if his arterial system had been acted upon by exposure to a mid-day sun. The sticklers, then, for the "dews of heaven," and the "bed upon the cool earth," may here indulge their predilections; but, for our own part, we give the preference to the house at night with horses free from disease.

The state of the horses, summered as we have now described, will in great measure resemble each other, although, as may be supposed, the one which has been kept on in his exercise will be most forward in condition. Neither of them, however, will have lost much of their proper form; but a distinction must be made in our proceedings with them, when preparing them for the forthcoming season. "Suffer a horse to be idle," says Mr Perceval (*Hippopathology*, p. 14), "to do little or no work, and feed him well during the time, and the redundant nourishment floating in his blood will be laid up in the form of fat; put the same animal to work, and that blood, which otherwise would have been turned into fat, will now be transformed into materials of strength." Here, then, it is evident that the horse which has been kept in exercise will require somewhat of a different preparation to the one which has remained unshod, and consequently idle. The first will require very little alteration in his proceedings until nearly the approach of the hunting season, as he will soon be prepared for quick work; but it will be by long-continued slow work, increasing in pace as his condition increases, that the second will be quite himself again, from the relaxed state of his muscles, somewhat redundant flesh, as well as his distended belly. In either case, however, there will be no occasion for all that physicking, galloping, and sweating, to get rid of bad, superfluous flesh, that the grass-fed hunter has been subjected to; for if the groom has done his duty by them, neither of these horses will have accumulated much more flesh than we like to see on hunters when they first begin to work, and when that flesh is good. We would have our second horse, the unshod one, taken into his stable early in August; and during the latter end of that month and the next, in addition to his daily exercise, he should, about three times in a fortnight, have a gentle sweat in clothes, which is best effected in a trot, in a large fallow field that has been lately harrowed down, and which is firm, not soft, to the tread.

But we fancy we hear the question asked, Is it not necessary to give physic to all hunters when the summer is past, and previously to their taking the field again in the winter? We answer, *No*. The principal end of physicking hunters is to allay excitement, occasioned by severe work and high keep; and the next, for the benefit of their legs. Thus, for example, as the first-named horse (the one that has been in gentle work throughout the summer), will not sweat so easily as the unshod one, a light dose or two of physic may be serviceable to him during his first preparation for the field, say in August or September, as the means of saving his legs, should he be a strong-constitutioned horse, and have thrown up too múch flesh. But there is no absolute necessity for physic at this period to horses that have been properly treated throughout the summer, and not suffered to get foul or fat; and it will be given with more advantage to them after they have been some time at work, or nearer to the commencement of the hunting season, which, after the manner of the racing stable, may be termed a second preparation. We think, however, we cannot do better here than to quote the following passage on this subject from the April Number, 1835, of the *New Sporting Magazine* (vol. viii. p. 353), as the ideas exactly correspond with our own.

"To horses summered in the house, physic is now only administered when it is wanted, as is the case with the race-horse; and the groom or his master ought to be able to say *when*. There are many directing symptoms with horses in work, which cannot escape an observant eye; and we do not, as formerly, wait for the swollen leg or the running sore. The barbarous practice, also, of three doses in succession (as was the practice with the grass-fed hunter on being stabled), 'the first to stir up the humours, and the last to carry them off,' with two strong urine balls to wind up, by way of a remedy for consequent debility, is also happily exploded. The strength of the dose is likewise greatly diminished, and consequently all danger is avoided. We take upon ourselves to say, there is no more risk attending administering physic to a horse, than there is in giving him a pailful of cold water, perhaps not so much;

Treatment of Horses.

that is, provided the drugs are good, and well put together. We, however, strongly recommend all sportsmen and others to obtain physic from the profession, as veterinarians bestow much attention on the making of it up, and obtaining the best aloes, in which there is much difference. The sooner it passes off the better; and this will be much expedited by three loose bran mashes on the day preceding the dose, and exercise previously to its working. Recollect there is no virtue in this case in the aloes, beyond doing its duty in clearing and cleansing the bowels. Calomel, when administered to the horse, should not be hurried, as it is intended to act upon the system, and should therefore be given twelve hours previous to giving the purge. Horses whose bowels are difficult to be moved, should be kept short of hay a day or two before they are physicked, with an additional allowance of bran mashes, and encouraged to drink before they experience nausea."

It may, perhaps, be well to state the "directing symptoms" for administering physic to the hunter, which are thus detailed by Nimrod. (*Condition of Hunters*, p. 173.) "Among the distinguishing symptoms of foulness in a hunter, are these:—He appears unwell, without any specific disease: his mouth is hot, his eyes look dull, and sometimes yellow: his coat loses some of its usual gloss, and stares between the hip-bones, and on the poll of the neck: his appetite frequently remains good, but he is more than usually anxious for water: his heels are scurfy, and sometimes crack: he stales often, but a little at a time: his urine is highly-coloured, and his excrements hard, and often covered with a slimy fluid: he is dull when at exercise, and frequently coughs without any appearance of having taken cold: he loses flesh, and looks dry in his skin: his legs and ears are often cold, the latter frequently wet after exercise, and sometimes deprived of part of their natural covering: his crest falls; the whole tone of his system appears relaxed; and, without his groom exactly knowing why, he is not the horse he was a week ago." To this we have nothing to add, unless it be to congratulate owners of horses on the terrors of physicking them having vanished with the present improved method of administering the doses; and on the fact, that only a few days' cessation from labour is now required to afford them this relief. We should say, that a hunter is never more fit to go through a sharp run, than on the tenth day after his physic has "set."

But we do not consider that we can close this part of our subject, without a few words on the treatment of the grass-fed hunter, as there are still some who yet abandon him to shift for himself in the summer, and are content to see him return to his stall in August, the very reverse of what he was when he left it in May. Nor is this the worst of it. He cannot be reinstated in the condition in which he was when he went out in May, until hunting is three parts over the following season. However, we will lay down what we consider the most likely plan to pursue, to fit him for the work he is intended for:—

From the redundancy of blood and humours, and distension of bowels beyond their proper size, which the grass-fed hunter acquires, all violent exertion must be avoided, until such obstructions are removed, which must be the work of time. It is in vain to attempt to hurry a horse in this state into condition, but the first step taken should be to have him clipped, for reasons which we shall presently give. Long-continued slow exercise is the chief agent in hardening his muscles, and strengthening his organs of respiration; but all galloping when in the state in which he will be for the first two months, to get off his flesh, is very highly to be reprobated, as his legs will surely suffer by it, if nothing else does. Two light doses of physic may be useful to him, if he have had none given him at grass; and care should be taken not to use the brush to his coat till the month of November be passed, in case he should not be clipped. Again, veterinary science has informed us, that danger always accrues to horses in the vicissitudes of heat and cold, from one state to its opposite; but more from the latter to the former, as an excitant to general inflammation. Horses taken from grass, then, should be put into very cool stables, and the fewer in one stable the better, for at least the first month. Windows should be left open day and night, merely taking the precaution of coarse matting, or any thing else that will stop the entrance of flies; and nothing does that better than matting, frequently saturated with water. Having been clipped, and kept out several hours in the day in slow work (which, by the way, grooms are too often shy of), increasing his pace gradually as his condition progresses, the grass-fed hunter may be brought fit to look at by the first week in November; but he will be at least by a stone a worse horse than he was when he was turned out. We are no friends to quacking in either man or beast; but, knowing that mischief to horses so frequently arises from a long respite from work in the winter, unless some preventive measures are had recourse to, we recommend the repetition of a light dose or two of physic to the grass-fed hunter during frost, or even during open weather, about Christmas.

Having recommended the fashionable operation of clipping to the grass-fed hunter, we will give our reasons for having done so. Nine horses out of ten, treated as he has been treated in the summer, break out into a cold sweat, after work, during the first part of the season, the natural consequence of debility; and the dew on their coat has all the chilling influence of a wet blanket on their body. The removal of the coat by the scissars, then, although it is no remedy for the former, prevents the ill effects of the latter; which, by producing cold on the surface of the body, occasions a determination of blood to the lungs, or other important viscus, and is a great enemy to condition. Although we deny the necessity of clipping a horse that has been *properly* summered (for, admitting that he may have a long coat, he will not in that case break out after work), we allow it the merit of expediting condition, by giving increase of bulk, and promoting the vigorousness of the horses' renovating powers; and, therefore, in this case useful. Looking at it, however, in another light, we find many objections to it; amongst the greatest of which is the deprivation of the protection of the coat or hair, to an animal so much in want of it as the hunter is, and therefore an outrage on nature. In fact, it is, to a certain degree, a substitute for good grooming, and as such will continue to be in favour with many grooms, as also with such of their masters as submit to be dictated to by them, or who may pay too much regard to appearances.

Having alluded to grooms, a remark or two may not be ill placed. Such of them as have the care of large studs cannot be expected to work, but to overlook those who are under them; and their responsibility is considerable. There is much in the choice of helpers; for none but persons who have narrowly watched it, are aware of the effects of a good dressing to a hunter, not merely in having his skin cleared from impurity, and in improving its elasticity, as well as the tone and colour of the hair, which may be termed the complexion of a horse, but it greatly promotes general health by its effect on the circulation of the blood, as well as all other secretions, and in bad weather is a substitute for exercise.

Good stables are indispensable to the well-doing of hunters, equally so with a comfortable house and a warm bed to those who ride them. Even the veterinary professors have at length acknowledged the benefit of the genial warmth of a stable to horses at work, although, in common with ourselves, they insist on the necessity of well ventilated stables. No doubt it is injurious to any animal to breathe an under-oxygenated air, and the effluvia arising from animal excretions are injurious to eyes and lungs. A hunter should live in a temperature of about 63° of Fahrenheit in

Treatment of Horses.

the winter, and as much below that point as it can be made in the summer, by means of exclusion of the sun, open doors, &c. But it is essential that a stable in the winter should not only be warm, but dry; and if not dry, the ground under and around it should be drained. A delicate horse never arrives at perfection of condition in a damp stable, and it operates powerfully against all others, often being the cause of fever in the feet. Stalls should not be more than six feet wide, nor raised towards the manger; but there should be a slight inclination in the flagging towards the centre of them, to enable the urine to find its way to a drain, which there always ought to be, as it contributes much to cleanliness, and consequently to health. "Loose places," or "boxes," as they are termed, are most desirable for all horses after severe work, and a celebrated veterinary surgeon (Mr Turner of Regent Street, London, to whom the public is so much indebted for his illustration of the navicular disease in the foot) has given it as his opinion, that if all horses were suffered to lie loose after work, there would not be half the cases of lameness in the feet that now occur. Desirable as such treatment may be, it is universally impracticable, on account of the space which large studs would occupy; but every sportsman should have boxes about his premises, and his hunters should be invariably put into them for two or three days after work. To their general use there is one objection, although not a serious one. Horses always lying loose are apt to refuse to lie down in stalls, when removed to premises where boxes cannot be had, but they become reconciled to them after a few days. It is, however, the opinion of a celebrated sportsman, that if a hunter should have stood his work ten seasons being always tied up, he would have stood it twelve if he had lain loose.

We quote the following extract from *Nimrod on Condition of Hunters*, on the subject of warm stables. After proving, by the fact of the horse degenerating in all cold countries, that warmth is congenial to his existence, he thus proceeds:—"They who attend to such matters will find, that the constitution and habit of a horse undergo a change when kept in a warm stable, favourable, no doubt, to the work he has to perform as a hunter in the stable of a hard-riding man. He is not that gross animal which he might otherwise be, if a hard feeder, and kept in a state more nearly approaching to a state of nature. This we may attribute to the increase of insensible perspiration occasioned by increased circulation, whereby the grosser particles of the body fly off and are got rid of. In this state he would bear some comparison with a well-fed English farmer, when put to perform feats of activity with a man of more refined habits of life, where nineteen times out of twenty he would be defeated." Again: "As there is an analogy between a man and a horse in work, let us carry it a little further, and ask, Whether, after a hard day's exercise in the winter, a man would recover sooner if he passed his evening in a warm room, or if he passed it in a bivouac, or in a room that was cold and damp?" He concludes by giving it as his opinion, that if it be possible to get a horse to look well in a cold stable, it is not in the power of a groom to put him into the height of condition in a damp one; and in this we heartily concur.

We subjoin Nimrod's plan of stabling for six hunters. "I would have," says he, "two four-stalled stables, in which I would keep only six horses, that is, three in each; and I would have a box at the end of each. If possible, I would have a southern aspect, with windows opening from the top or downward, or else on a pivot in the centre, and placed so high in the wall, that, when open, the air may be circulated through the stable, without affecting one horse more than another, and the height of the interior should be only twelve feet in the clear. I would have the stalls paved nearly flat, with only a trifling inclination to the centre; in each of which there should be a small grating over the drain, and the stalls should be no more than six feet wide. There should be at least twelve feet behind the horses, and the exterior walls and doors should be very thick. The wooden partition-walls of the boxes should be only nine feet high, with wooden bolts to the doors; and each box should not exceed ten feet square. The saddle-room, well fitted up with saddle-cupboards, boiler, &c., should be in the centre of the building; in the front of which there should be a passage, under cover, for horses to stand in when their legs are washed. Of ventilation I say nothing, that being a matter of course; but I would have the sides of the stalls nine feet high at the head, with small iron racks, and pillar-reins for each horse to be dressed in. I should be very particular about the stall-posts, for these are frequently the cause of severe injury. When I went to see the King's stables at the palace at Pimlico, I was astonished to see almost every other horse in them, with capped hocks. On inspecting the stall-posts, I perceived the cause. They were of fluted stone, and with angles, which proved that Mr Nash (the architect) knows nothing about the inside of stables. Stall-posts should be made of wood, quite smooth and circular; and they should extend to the ceiling, or be at least ten feet high."

Paddocks.—Some persons turn their hunters into the fields in the summer, because they have no small paddocks, or any outlets to their buildings, and are averse to their horses remaining all the year round in the house. Nothing, however, is easier than making temporary paddocks, or outlets that will restrain stallions, or any horse that may be put into them, without the chance of their breaking out of them. Let a small space, say thirty or forty yards, be hurdled around, and the hurdles lined with faggots reared up from seven to eight feet high. The faggots will be all the better for the exposure to the air during a summer; and as horses cannot see through a fence of this sort, they will never attempt to break through it.

Food.—The proper feeding of hunters has much to do with their condition, and likewise with their remaining sound. Food should be proportioned to work, and it should also be of the very best quality. Hay that has been much heated in the stack is above all things to be avoided, as, from its powerful diuretic properties, it debilitates, and creates thirst; and mow-burnt or heated oats are equally productive of mischief. Eight or ten pounds of hay per day are as much as any hunter should eat, and that which is produced on dry upland ground is best. Indeed, we are far from thinking that rich meadow hay, finely scented as it is, and apparently so full of nourishment, is fitted for any description of horse that is required to go fast, and we are quite certain that thousands of horses are destroyed annually by the effects of hay and water. The latter cannot be too soft, and when not so, it should be kept in the stable some days previous to use, and with a small portion of bran in it. Mr Percival (*Hippopathology*, p. 25.) mentions forty-nine horses being killed in one stud, in France, by a disease produced by eating bad hay and oats.

But nothing puts the groom's knowledge of the art of feeding hunters more to the test, than the management of such as are either naturally thick-winded, or afflicted with chronic cough; and as in man, the digestive organs are oftener than any other disordered, so the respiratory organs in the horse are the most common seat of disease. It is, however, in the power of a groom, by great attention to feeding, keeping the habit of body from becoming foul and plethoric, and well regulated work, to make horses of this description tolerably fit to go with hounds; whereas in bad hands, they would be nearly useless, at all events dangerous to ride. Such horses are generally hearty feeders, and when so, should have a setting muzzle, as used with race-horses, put on them on the night before hunting, unless they have been out with hounds within three days. Water also should be sparingly given to them on that day, and not

Treatment of Horses.

ment after three o'clock P. M. Frequent mild aperients, or alterative medicines, are very efficacious here; for as, in the human subject, the lungs often become the seat of disease as a second cause of indigestion, the state of the digestive organs should be minutely attended to with horses of this description.

A broken-winded horse is never seen in a stud of hunters; but Nimrod's remark on this subject is in accordance with what we have now written upon it. "Most veterinary surgeons," he says, "attribute this disease to the consequences of high keep. Here, no doubt, they are in a great measure correct; but if good grooming were not for the most part a match for the effect of high keep, what would be the fate of our race-horses, which eat almost as much corn as they can swallow from the first month of their existence? Amongst them a broken-winded horse is a rarity."

Many nostrums are prescribed for thick-winded horses, amongst them, carrots in the winter, and green meat in the summer. We approve of a few carrots in the winter, but object to green meat, unless in small quantities. Is not flatulency the distinctive feature of a disordered respiration? And what promotes that equally with loading and distending the stomach with green food? The small dimensions of a horse's stomach, evidently shew what nature intended him for, namely, *to go fast;* and the pathologist would very soon convince us that, in proportion as that organ is distended, will the respiratory organs be oppressed. Hence the indispensable practice of not allowing hunters their usual allowance of food and water on the morning of hunting; as also of putting the setting muzzle on the racer the night before he runs. The food most proper for all horses, but particularly for such as are not perfect in their wind, is that which contains most nourishment in the smallest compass or space.

But we must not overlook the treatment of the *sound* hunter before and after hunting; as we consider the lives of more than half of those hunters which have been lost from the effects of severe chases, to have been lost from want of knowledge of how they should have been treated, at either the one or the other of these periods. Nimrod, in his letters on this subject, doubts whether it be in the power of hounds to maintain a chase long enough to cause the death of a horse, fairly ridden with them, provided that horse have been properly treated in the summer, and is in what is called strong work, or quite fit to go, on the day of the run. Without stopping to argue this point, which is not capable of proof, we will proceed to shew in what state a hunter ought to be taken into the field, to meet foxhounds, giving him fair play; and the man who takes him there when not fit to go, must always be prepared for the consequences.

We consider a hunter, in proper condition, equal to at least three days' hunting in a fortnight, taking the average of sport, which will, of course, at some certain periods, send him oftener into the field in one given time than in another, as, after a severe day, he should have a week's clear rest. But since the second-horse fashion has been so general, it is impossible to speculate on this point, as it so often happens that one of the two horses the sportsman sends to cover, returns home without having done much. The chief point, however, to be insisted upon is, that the hunter should have a good gallop, causing him to sweat freely, on the day before he goes to hounds, and if for half-a-mile on rising ground, it will be more favourable to his wind. His food on that day should also be attended to, in reference to his constitutional peculiarities; for, if not the best winded horse in the stud, or given to throw off his meat on his road to cover, he should have no water after three o'clock the preceding afternoon, with the exception of a few swallows, to make him relish his corn, on the morning of hunting. Sending hunters out now with full bellies has no excuse; whereas one was found for it, when they left their stables five hours sooner in the morning than they do at present; and returned to them often five hours later. We allude to past days in which there were few artificially made covers, and when foxes were found by the "drag," through long chains of woods, and certainly ran over much more ground than modern foxes do, which, being generally bred near game preserves, run shorter, and are not so stout as formerly.

After Hunting.—The treatment of a horse now, will depend on what he has been doing. If not a severe day, no further notice of him is requisite, than to ascertain whether he feeds as usual; and if not an alterative ball,[1] with a liberal allowance of tepid water, will soon restore his appetite, by allaying the over-excitement that has checked it. It is after a severe day's work that danger to a hunter is to be apprehended, the consequence of over-excitement of the vascular system, and he should be in this case narrowly watched. If merely fatigued, such are the restorative powers of the animal, rest, in a large loose box, with an hour's exercise daily, in the open air, will soon bring him about; but we should be on the alert against fever. Here, however, we generally have notice,—some directing symptoms which cannot be mistaken, such as hurried respiration, extreme thirst, restlessness in his stall, a considerable relaxation of the muscles in the interstices of the hips, reddened eyelids, and a quick pulse. But unfortunately for hard-riding sportsmen, it too often happens, that such is the rapidity with which what is termed accidental inflammation takes place in the horse, that the most prompt measures will not always arrest its progress, and the most common termination of it here is in the feet. Not only does the animal suffer great pain, but should he not cast his hoofs entirely (the fore-feet are most commonly affected), he becomes, what is called, pumice-footed, and of no value afterwards as a hunter. Knowing this to be the case, we are advocates for some prophylactic measures to be taken after a very hard day; something repellant and sedative administered, which may not only prevent an inflammatory attack, but, by cooling the system, and consequently restoring the appetite, enable the horse to go sooner into the field again, than if he had been entirely abandoned to his own restorative powers.

But the most critical period with the over-ridden hunter is, when he first appears to shew distress, which he often does on his road home, or even before he quits the field; and here mistakes have been made, which have caused the death of many a good animal. In the first place, his rider fancies it necessary to drag him home, perhaps many miles on a cold winter's evening, to "his own comfortable stall," than which, just at this time, a large and cold stable, and the first he could be put into, would be far more beneficial to him. Again, he says, "I'll not do any thing to him till I get him home, when I will have him bled;" whereas, since all horses that die from exertion beyond the limits of vital power, die from suffocation, it will then be, in all probability, too late, as *instant* relief is wanted. A stimulating cordial is likewise at this time good (a pint of sherry as good as any other), but both are bad if inflammation has commenced; also keeping up a strong determination of blood to the surface by friction of the body, head, and legs, with warm clothing afterwards on the body and head; a well littered down stall, with plenty of fresh air. A gallon of blood should be at first drawn; and if the increased action of the heart and arteries continues, the horse should be well blistered behind the elbows, and lose another gallon of blood. Blood-letting from the foot-veins, is also highly to be recommended in cases of extreme exhaustion, after a hard day with hounds. It is a very simple operation, and can never do harm; but we advise it to be performed by a veterinary surgeon.

---

[1] The following alterative and sedative medicines are found efficacious at this time:—Cinnabar of antimony, 3 oz.; balsam of sulphur, 2 oz.; camphor, 1 oz.; nitre, 4 oz. To be made into ten balls; one ball a dose. These are known among grooms by the term "red balls."

Treatment of Horses.

They who have never before experienced it, may be alarmed by an inward noise in a distressed horse, which may be mistaken for a beating of the heart, whereas it proceeds from a convulsive motion of the abdominal muscles, or muscles of the belly. It is, however, a symptom of deep distress, and is only relieved by relief given to the lungs, by bleeding and other preventive means.

Treatment of Horses' Legs.—We have already said, that the management of horses' legs forms part of the science of the stable, and a most important part too. It is no where so well understood as in racing stables; but from the violent nature of his work, the hunter is equally indebted to it. The barbarous practice of blistering all four legs previously to turning out, is now happily exploded; but as in less violent exertion than following hounds, a certain insecurity from accidents is inseparable from the delicacy of all animal structure, the legs of hunters will occasionally fall amiss. It being useless, however, without stating the extent of the injury, to talk of prescribing remedies, we have only to state, that a very efficient one has been found for the torturing one of firing, in many cases where the actual cautery was considered as the only one. For example, for ligamentary enlargements, cases of enlarged joints, tendons shewing symptoms of giving way, or any other appearance in the limbs, of a departure from their primitive tone and vigour. This consists in the application, during the non-hunting months, or any other period of rest, of the mercurial charge, in either of the following forms. It is made up by Mr Field, veterinary surgeon of London, and no doubt by others in the profession, in a strong adhesive form; or, at a distance from the metropolis, it may be applied, as recommended by Mr Kueny of Nottingham, who is constantly in attendance upon the studs at Melton Moubray, in Leicestershire. It consists of the common mercurial *plaster* (not *ointment*) of the shops, made up according to the London Pharmacopœia; and in the proportion of half-a-pound to a leg, applied in a warm and consequently liquefied state, and when covered by deer's hair, bound to the limb by means of a linen roller. At the end of a fortnight, the stitches of the bandage being decayed, the charge will slough off, when another, if necessary, is put on. It is to the highly absorbent property of mercury that the benefit here derived is to be ascribed; and it is no small recommendation to it, that, in addition to the general restoration of the limb, the painful operation of the actual cautery, as also the blemish occasioned by it, are avoided.

It is, however, a well known fact, that hunters will work and stand sound, for many successive seasons, with legs apparently much out of form. Enlargements take place in the sheath of tendons after strains; also from blows, where the parts become lined by a thick coat of lymph; and sometimes the body of the bone itself is found thickened, from a deposition of bony lamina over the original bone. When all this has been in progress, we question the propriety of any active measures, unless, as is generally the case, a feeling of soreness is expressed after work, by a shifting, or favouring of the limb, or limbs, in the stall; or by a "feeling" manner of going on first quitting the stable. When legs are really callous, little impression can be made upon them, unless by active measures; but physic, rest, and good grooming, are the best preservatives of these most essential members of the horse's frame; with the friendly auxiliaries of hot-water, flannel bandages, and loose boxes, after severe work, and good shoeing at all times.

The Foot.—Owners of valuable horses may congratulate themselves on the assurance that, by the aid and extended influence of veterinary science, they have no longer to apprehend injury to the feet from the mere application of shoes. On the contrary, they may rest satisfied that, provided no internal disease attack them, from over-excitement by work (and that often is created on ground where shoes would be unnecessary, such as crossing a very deep country), they will be not only as sound and healthy, but *in better form*, from having been properly shod, than if they had not been shod at all. Some hoofs, however, having a greater disposition to secrete horn than others, and thus called strong feet, should never remain more than three weeks without being subject to the drawing knife of the blacksmith (the ruinous butteris is now put aside), and the shoes properly replaced. Neither should stopping with damp tow be omitted; as moisture, *not wet*, is beneficial to the health of the foot. Here then, again, are at once apparent the evils of the out-of-door summering of hunters. The foot of a horse so exposed, is at one time saturated with wet, and at another exposed to a drying wind and a burning sun, the contractile powers of which upon horn, are too well known to require comment. Do what we may, however, horses that are required to "go the pace," will always be more or less subject to diseased feet, quite unconnected with shoeing; and against such diseases there are but two precautions on which much reliance can be placed: First, let hunters be well prepared for their work, and properly treated after it; and, secondly, let them have sufficient obliquity of pastern-joint (in our opinion one of the most important points in the whole structure of the horse), to break the force of concussion; which, together with over-excitement of the vascular system, is the parent of that irremediable disease of the navicular bone, formerly called "founder;" and by the wiseacres of old times, "chest-founder," because the muscles in that part wasted, from the inability of the suffering animal to exert them. The posture of a horse in his stall, when afflicted with this complaint, or fever in the feet, is too characteristic to be mistaken.

We have only one more remark on shoeing. In following hounds across deep countries, hunters are apt to strike a hinder foot against a fore foot, and inflict a severe wound. There have, indeed, been many instances of the total separation of the back sinew by this, often unavoidable act, particularly in leaping brooks. It was formerly very generally believed, that the blow was inflicted with the *toe* of the hinder shoe, to obviate which, shoeing smiths were ordered, by hunting grooms, to let part of the hoof protrude over the front of the shoe, but still the evil continued. It was, however, asserted, in the letters of Nimrod, that it was by the *inside edge, or the rim of the hinder shoe*, and not by the toe, that the act of over-reaching was performed. This was at first doubted, but experience has confirmed the assertion; and we have reason to believe, there has not been an instance of serious mischief by *cutting*, from an over-reach, since the inside edge, or rim, has been rounded off, or bevelled. Indeed, a moment's reflection would dispel all doubts on the subject; for the obtuse form of the toe of a horse-shoe could not inflict the severe wounds we have seen inflicted (often cutting off part of the fore-heel); whereas the inside rim of a worn shoe is nearly as sharp as an ordinary knife. Besides, the act is performed *after* the hinder-foot has overstepped the fore-foot, and therefore cannot be performed by the toe, but in the act of drawing the hinder foot back, after it has overstridden its bounds. Bruises, from over-reaches, still occur, which, though sometimes serious, are comparatively, with cutting, harmless, as fomentation, and a few days' rest, will effect a cure.

The action of the hinder leg reminds us of one useful hint to grooms travelling hunters on the road. If we follow a well-formed horse, with the free use of his limbs, on a road upon which his footsteps are imprinted, we shall find the hinder foot oversteps the fore-foot in the *walk*, but falls behind it in the slow *trot*. Exclusive of relief to the muscles by change of action then, it is safer to vary the pace from a walk to a slow trot on a journey, as causing less fatigue to the hock-joint, by which curbs and spavins are frequently thrown out. Add to this, the slow trot is the safest pace a horse goes, because his step is shortest.

(B. B. B. B.)

HORSEMANSHIP.

As to the question, Who was the *first* horseman? it would be in vain to inquire, for even the writers of ancient fables do not agree upon the point. By some it is pretended that Bellerophon first mounted a horse; that Pelethronius first bridled him; that he was harnessed by Erichthonius, and fought upon by the Centaurs of Thessaly. But quitting fiction, we learn from the Sacred Writings, that to Egypt we are indebted for the equestrian art, from which country, by the aid of the colonists who emigrated from it and from Phœnicia, it was introduced into Greece (perhaps by Erichthonius, fourth king of Attica), where it attained to great perfection. Although there was no cavalry employed in the Trojan war, equestrianism must have been much practised and well understood in Homer's time, which is at once proved by a reference to his works. In the fifth book of the Odyssey, the shipwrecked Ulysses, tossed by the waves on a plank, is compared to a skilful horseman on an unruly steed; and in the fifteenth Iliad, we find one man managing four horses at once, leaping from the back of one to another, at their full speed. Herodotus (in *Thalia*) speaks of hunting on horseback in the time of Darius, even descending to the particulars of an accident in the field to the noble satrap of Persia; and likewise the same writer (in *Melpomene*) mentions the Amazonian women hunting with their husbands on horseback. Xenophon also says that Cyrus did so, when he exercised himself and his horses. Again, with reference to those early times, we should not pass over the introduction of horses and horsemanship into the public games of Greece, and particularly the Olympic Games, which, according to an expression of Pindar, as far transcended all the others as gold is superior to the baser metals.

From the same authority we learn, that the Ethiopians and inhabitants of India, as cavalry, formed part of the expedition of Xerxes against the Greeks. But it appears that the Arabs and the Parthians, who afterwards became so famous for their equestrian accomplishments, were ignorant of the art at the period in question; at least both these nations fought under Xerxes, the former on camels, and the latter on foot. The Persians were more celebrated for their horses than for their riding. According to Athenæus, they were more solicitous of their ease and safety, than anxious for reputation of boldness and dexterity in horsemanship. The Scythians and the Sarmatians were both famous about this period, as well for their breed of horses as for their skill in riding them. In fact, so renowned were the former people, that, according to Gibbon, they were supposed by strangers to perform the ordinary duties of civil life on horseback; "to eat, to drink, and even sleep, without dismounting from their steeds."

The people of Mauritania, Numidia, Massilia, Nasamonia, and other adjacent parts, are also spoken of as having possessed breeds of excellent horses, but were still more distinguished for their singular mode of managing them (on the authority of Livy, and Cæsar) without the aid of a bridle, and even in battle by means of a small switch or wand, turning them to the left by striking on the right side of the head, and *vice versa;* and stopping them by striking the front of the face. These practices are also confirmed by Ausonius, who celebrates the Emperor Gratian as having excelled in them. All we have to remark here is, that we are glad such practices are abolished, not only on our own account, but for the sake of horses, who must have been greatly tortured before they were brought to such a state of obedience as to be ridden *infræni* (without bridles), as Virgil says of the Numidians, and this in the confusion and excitement of a battle. There is an elegant passage on this subject in Lucan's *Pharsalia*, descriptive of the several tributary nations which Juba took into the field in the cause of Pompey, against Curio's army, which he entirely defeated.

> "Autololes, Numidæque vagi, semperque paratus
> Inculto Gætulus equo," &c.

Thus translated by Rowe:—

> "With him unnumber'd nations march along,
> Th' Autololæ, with wild Numidian throng;
> The rough Gætulian, with his ruder steed;
> The Moor, resembling India's swarthy breed;
> Poor Nasamons, and Garamantines join'd;
> With swift Marmaridans, that match the wind;
> The Marax, bred the trembling dart to throw,
> Sure as the shaft that leaves the Parthian bow;
> With these Massilia's nimble horsemen ride;
> They nor the bit, nor curbing rein provide,
> But with light rods the well-taught coursers guide.
> From lonely cots the Lybian hunters came,
> Who, still unarm'd, invade the salvage game,
> And with spread mantles tawny lions tame."

The Greeks transmitted the art of horsemanship to the Romans, who soon equalled, if they did not excel, their instructors; and nearly one of the first public acts of their first king was to establish the equestrian order, the second order in Rome; the *equites*, or horsemen, being placed far above the commonalty, and next to those of the highest quality and fortune in the state. In short, were proof wanting that horsemanship, as an accomplishment, was held in the greatest esteem in the early ages of the world, it would be found in the fact of the accomplished Cicero (*De Off.* l. 2, c. 13) telling his son Marcus, with the vanity that now and then breaks forth in the splendid effusions of that great man's pen, that the eyes of the world were upon him, on account of his father's fame; and that he had received the praise of the whole army for his excellence in *riding.* But the exercise and art of horsemanship occupied much of the study and attention of the Roman youth; and we find Horace inviting them to the practice of it, in the eighth ode of the first book.

Descending from the heroic ages, in which the earliest history we possess informs us the art of horsemanship was in full force and vigour, to comparatively modern times, the first notice we find in our own history of the art of riding horses, is in the tilts and tournaments; the earliest mention of which we find in the French historian Nithard, who reports, that, at an interview which took place at Strasburg between Charles the Bald and his brother Lewis of Germany, the followers of both these princes fought on horseback; and, by way of marking the period, it may be observed, that Charles the Bald succeeded to the throne of France A. D. 840. Ducange affirms, that these combats were for some time peculiar to France, and expressly called French combats, *conflictus Gallici.* Scarcely any thing distinct, however, is known about them till we find them practised in England, about the year 1140, in the reign of Stephen, after which time they became general all over Europe, particularly in England, where they were displayed on all great occasions. The spots most famous for them in London, were the Tilt-Yard, near St James's Park, and Smithfield; which the neighbourhood of the latter place confirms, by the names of the streets, such as "Giltspur," "Knight-rider," and so on. They are also known to have been practised on the spots now called Cheapside, Barbican, and Bridewell; and to have been exhibited in considerable splendour in various parts of the country besides, which a reference to the highly popular novel *Ivanhoe* will show. These were the days when "to witch the world with noble horsemanship" was one of the chief accomplishments of a gentleman; in which the management of the horse and the lance was amongst the principal requisites of knighthood; when the contest, both in real and in mimic war, was decided by the superiority of such means; the days of chivalry, in fact, which, as a well-known historian says of it, in his portrait of the character of a perfect knight, the accomplished Tancred, "inspired the generous sentiments and social offices of man, far better than the base philosophy, or the baser religion of the times."

The manège, and more especially the *high* manège-riding, is now nearly out of use. As Colonel Peters observes (*Treatise on Equitation*, p. 236, London, 1835), "In the riding-houses, for mere pleasure, or military purposes, very little of the manège riding is requisite. The instructions for a manège rider and his horse go far beyond those required for a military horseman and his horse. The confined airs, cadences, or paces of the manège, are not calculated for the duty of a pleasure or a military horse; the sensitive, delicate hand, and its aids, of the manège-rider would not do for a soldier. It should, therefore, be well understood, that, although a soldier's horse should be quick and ready, it is not required to have him so much on his haunches, nor so fine in the mouth, as the manège-horse must be. If a military horse be put in his proper equilibrium, it is all that is requisite; he should not lose that boldness and freedom of action, which is generally so much admired, and so necessary, in the different duties that a military rider is called upon to perform." We are glad to be enabled to state, on such high authority as that of Colonel Peters, that the exercise of the manège is by no means necessary to the education of the horse, for any purposes which require his being trained in the school, as it is impossible to read the instructions of the masters of that art, as practised so generally at one time, without being satisfied, that the greatest severity must have been resorted to in their lessons. It is a maxim in horsemanship, and a good one, "that a horse must never do any thing of his own head, but in obedience to his rider;" but to call upon him to force himself into the unnatural positions which the *Manège d'Ecole* requires, is, in our opinion, labour very ill bestowed; and as for the gracefulness of his action, so much insisted upon by the manège-riders, we think it is never more fully displayed by him than when nearly in his natural state. There is, however, we admit, something pleasing in the associations of the horse highly caparisoned, as well as the airs of the manège, with grand and imposing spectacles; and there are several passages in the third Georgic of Virgil, which shew that the manège was found out earlier than many persons may imagine.

Not only is good horsemanship well suited to the pith and nerve of the English character, but it has always been considered as one of the corporeal accomplishments of a gentleman. Thus Clarendon, in his character of the Duke of Newcastle of his day, says of him, that "he was a very fine gentleman, active, and full of courage, and most accomplished in those qualities of *horsemanship*, dancing, and fencing, which accompany a good breeding; in which his delight was." But there are other than mere personal advantages attending good horsemanship. It is the habitual contempt of danger that ennobles the profession of the soldier; and horsemanship, as practised in England at present, and with the *esprit de corps* of the several hunts, tends much to the same end. Those who pursue it in the field, learn to expose themselves to danger with less reluctance, are less anxious to get out of it, or given to lose their presence of mind when in it, than persons whose pursuits have been of a different turn; in fact, it may be said to increase natural courage. Such persons, again, as merely ride on horseback for exercise, find in it the great preservative of health. Nay, more than this, persons of tender constitutions have surmounted the weakness of their nature entirely, by horse-exercise and hunting; in proof of which, many cases could be quoted. The following, of a patient of the celebrated Dr Sydenham, is perhaps as conclusive as any other:—A gentleman, a relation of the Doctor's, who was brought so low by consumption, that there appeared to be no possibility of a recovery by medicine, was induced by him to try horse-exercise, and a journey to his native country. On leaving London, he was so weak as to be lifted on his horse, and was refused admittance to the first inn he stopped at, being supposed to be in a dying state. Notwithstanding, he persisted in riding, by easy stages, to Exeter, and gained so much strength by the way, that though one day his horse lay down with him, in some water, and he was forced to pass many hours in his wet clothes, he not only sustained no harm by the accident, but arrived at Exeter greatly recovered. Thinking he had gained his point, he left off horse-exercise, and had a relapse; but, on betaking himself again to the saddle, he obtained a perfect recovery. Nimrod, in one of his hunting tours, says, "My time was almost divided between my saddle and my bed; but I never knew what it was to be fatigued when I lived temperately, and went early to rest. Indeed, such a life bade defiance to disease. A celebrated physician of the last century used to recommend riding on horseback to his patients. 'Live,' said he, 'in a saddle.' That riding is the most wholesome of all exercises, I have little doubt. Despite of all the vile stuff that finds its road down his throat, who ever heard of a bilious post-boy?" To this might be added, the no small advantage a person mounted on horseback derives, from breathing a purer air than when on foot, and consequently nearer to the ground. The salutary effect of the motion of a horse, also, on a sluggish or diseased liver, is acknowledged by all medical men.

We shall now take a view of horsemanship in the only forms in which it is at present applied to any useful or pleasurable purposes; namely, military, hunting, racing, and on the road, leaving the art of instructing horses for the Circus to those who find it profitable to fit them for it, which we admit they do to very great perfection, though we fear not without the necessary privation and punishment unavoidable, we believe, in such kind of instruction; or, in other words, in making animals perform far more, we conceive, than the Creator of them ever intended they should perform.

The military seat approaches nearer than any other to that of the manège; and, by reason of the horse-soldier having, in general, but one hand to hold his bridle with, is one which gives him great command over his horse, without disturbing his seat. He sits well down in his saddle, on his fork, or twist, with his body erect, and in perfect equilibrium with his horse; his legs well stretched down the sides, with a firm pressure of the calves, as well as of the knees and thighs, and the feet firm in the stirrups. But it is not by any *one* of these aids that he becomes a good horseman. He must be in perfect unison, as it were, with his horse's actions and paces, to maintain a good and graceful seat; and, in proportion to the just balance of his body, will he be able to have a steady hand, a point of vast importance to the dragoon. The importance of this balance, and keeping himself in a proper equilibrium with his horse, is increased by the fact of his not being allowed to rise to the horse's trot, and therefore requiring a still finer use of the bridle hand. "The man who rides with the aid of the proper equilibrium," says Colonel Peters (p. 234), "will, in case of necessity, know when to apply the strength he has retained with a steady, light hand, and govern every motion according as he finds it necessary for his purpose; play light with his own weight upon the saddle (by a gentle spring in the instep of both feet on the stirrups), with an easy pressure of both thighs, knees, and calves of the legs. When the horse jumps or plunges, then these aids are also requisite to keep the seat; but, in an easy, steady pace *forward*, it is most particularly to be pointed out to a young man, and cannot be too often repeated, that, to become an easy, elegant, or proper horseman, he must learn to ride with comfort and pleasure to his horse as well as to himself; he must learn to seek his balance from his hip upwards, to keep the body with a slight inclination backwards from the perpendicular, and balance himself thus gradually on his horse in all the different paces; which, of course, cannot be expected all at once. A man that rides by the force of his knees alone, shaking his arms and hands, although he rides his distance in the same period of time that the good rider would, yet he cannot be said to ride his horse, or to have any part of his body in the proper equilibrium; but the man who rides his horse with a light, steady hand, and elastic body (which, when disturbed even, has the power of restoring itself to its former seat), in unison with the horse's action, may be truly said to ride in the proper equilibrium."

It would much exceed the limits of this article, were we to enter into the detail of the military riding-school; neither is such a task necessary, from the number of works that have been published on the subject, and also from the various changes in the system that are perpetually occurring, according with the fashion of the day. We shall proceed, then, at once to the general principles of horsemanship, as applicable to the road, the hunting-field, and the race-course, commencing with the road.

The act of mounting may be called the first step in practical horsemanship. With horses perfectly quiet, it matters little in what manner we approach them; but in every thing that relates to horses, a certain precaution is necessary. Let the person who is about to mount, then, walk up to his horse, not directly in his face, lest he may alarm him, nor behind him, lest he may strike at him, which he would thus give him an opportunity of doing. Let him rather approach him on the left side, over against his shoulder, inclining something more to his head than to his flank. In the summer time, when the flies are troublesome, this caution is not ill bestowed, because the quietest horses will sometimes strike out, sidewards, after the manner of cows, to rid themselves of their tormentors; and many a man has been injured in the abdomen, or thigh, from this cause. Old writers on horsemanship recommend the horseman, when about to place himself in the saddle, after having put the left foot firmly into the stirrup, to take the reins and the pummel of the saddle in his left hand, and laying his right hand fast upon the hinder part of the saddle, thus to spring into his seat. We should prefer his taking a lock of the mane, together with the reins, into the left hand; because, if he be a man of any considerable weight, his having recourse to the saddle for all the assistance he may require, would be very likely to displace it, especially as no horse in the hands of a good horseman is now tightly girthed.

When he is mounted, the proper adjustment of his reins is the next thing to be attended to. If a single-rein bridle, he has nothing to do but to draw the reins with his right hand through his left, till he finds he has got hold of his horse's mouth equally on both sides of it, when he shuts the left hand, letting the little finger separate the two reins. The same should be done with a double-rein bridle, only observing, as they are drawn through the hand, that the horse's mouth is to be consulted, as to whether that attached to the bridoon or to the bit is the one required to be first acted upon. Many an inexperienced horseman has met with accidents from want of a proper discrimination as to the right use of the reins, when mounted on high-spirited horses, with finely made, that is to say, highly susceptible, mouths, and unused to a rough hand. The bridle reins should be held at a convenient length; for, if short, they will discompose the attitude of the body, by pulling the left shoulder forward; and they should be held with a firm grasp, dividing them, as before mentioned, with the little finger. When a horse pulls at his rider, he should advance his arm a little, but not the shoulder, towards the horse's head, raising his hand towards his breast, and the lower part of the palm rather than the upper; but he should not shorten the rein in his hand, if he can command his horse without it, or he may lose the proper *appui*, or bearing of his mouth. Old writers recommend the bridle-hand to be held perpendicular, the thumb being uppermost, and placed on the bridle. Modern practice is in favour of the knuckles being uppermost. The perpendicular hand may do very well in the school, or with the severe bit of the highly-drilled dragoon horse; but no man could ride a free-going race-horse over a course, or a hasty hunter over a country, in that form.

In dismounting a horse, the bridle and mane should be held together in the left hand, in the same manner as in mounting. Unless the horseman be very active, he may put his right hand on the pummel of the saddle, to raise himself, previously to throwing his right leg back over the horse; when, by grasping the hinder part of the saddle with the right hand, he lets himself down with ease. The right leg, however, should not be bent at the knee, or the spur may strike the horse's side, in the act of being thrown backward.

The first step towards perfection in a horseman, is to know and to feel how his horse is going; but this must be the result of some practice and experience. A horse may not only gallop false, that is to say, if going to the right he leads with the left leg, or, if going to the left, he leads with the right; but he is at times what is called disunited, that is, he leads with the opposite leg behind, to that which he leads with before. In both these cases, either in the school, or in his exercise, he must be stopped, and put off again properly. The method of effecting this, is by approaching your outward leg, and putting your hand outwards; still keeping the inward rein the shorter, and the horse's head inwards, if possible; and if he should still resist, then bend, and pull his head outwards also; but replace it again, bent properly inwards, the moment he goes off true. A horse is said to be disunited to the right, when going to the right, and consequently leading with the right leg *before*, he leads with the left leg *behind;* and is said to be disunited to the left, when going to the left, and consequently leading with the left leg *before*, he leads with the right *behind*. A horse may at the same time be both false and disunited; in correcting each of which faults, the same method must be used. He is both false and disunited to the right, when, in going to the right, he leads with the left leg before, and the right behind; notwithstanding that hinder leg be with propriety more forward under his belly than the left, because the horse is working to the right. And he is false and disunited to the left, when, in going to the left, he leads with the right leg before, and the left behind; notwithstanding, as above, that hinder leg be with propriety more forward under his belly than the right, because the horse is working to the left. A horse will also occasionally both trot and walk false.

Although the foregoing remarks apply principally to the working of a horse in a circle, or in the school; yet, as all horses will occasionally get disunited in their action, when going straightforward, it is very necessary that horsemen should know when they become so, and be able to set them right. Such action is extremely unpleasant to the rider; and likewise so much so to horses themselves, that they will not continue in it long, but generally quit it of their own accord.

The Seat.—It was well observed by Don Quixote, in one of his lectures to Sancho, that the seat on a horse makes some people look like gentlemen, and others like grooms. But a wonderful improvement has taken place within the last half century in the seat on horseback, of all descriptions of persons, and effected chiefly by the simple act of giving the rider a few more inches of stirrup-leather. No gentleman now, and very few servants, are to be seen with short stirrups, and consequently, a bent-knee, which, independently of its unsightliness, causes uneasiness to the horse as well as to his rider; whose knees being lifted above the skirts of the saddle, deprive him of the assistance of the clip, by his thighs and legs. The short stirrup-leather, however, was adopted with the idea of its giving relief to the horse, although a moment's consideration would have proved the contrary, and for this reason; the point of union between a man and his horse, as well as the centre of action, lies just behind the shoulder-blades, which, as must be apparent to every one, is the strongest part of the horse's body, and where the sack of wheat or flour is placed by the farmer, or the miller. With short stirrup-leathers, the seat of the rider is thrown further back on the saddle, instead of being exactly in the centre of it, and consequently his weight thrown upon the part approaching the loins, the weakest part of the body, and very easily injured. From the same mistaken notion was the saddle formerly placed nearly a hand's-breadth from the shoulders, which, of course, added to the mischief; but modern practice has entirely remedied this, as it is now placed as near as possible to the shoulder-bones, so as not to interfere with the action of them.

Next to the advantages of a good seat to the horse, stands the ease and elegance of it in the rider. In the first place, what is natural is easy, and there must be no formal stiffness of the body of a man, or of a woman, who wishes to look well on horseback. When we see a man sitting as upright as if he were impaled, and his body not appearing to yield at all to the motion of his horse, we cannot fancy his having a good hand upon him, because he cannot be in unison with him in his action; neither can he be firm in his seat. But to some persons a good seat is denied by their shape and make. For example, a man with short legs with large calves, and very round thighs, cannot sit so close to his saddle, as another whose legs are thinner and longer, and of course yield him a firmer clip; and whose thighs, instead of being round, are hollowed out on the inside, as we see in the form of our most eminent jockeys. The seat of the short-legged, large calved, round-thighed man, has been jocularly termed the "wash-ball seat," and not inaptly neither, for, like a wash-ball in a basin, he is seldom at rest in his saddle, from the absence of a proper clip. The thighs, in fact, are a most essential part of the horseman in giving him a good, graceful, and strong seat, as on the form of them depends greatly the good or bad position of the knee, which is a point of the utmost importance, not only to the eye, but to the firmness of his seat. The thighs, in fact, should be applied to the saddle and to the sides of the horse, chiefly by their inner surfaces, or the knees and toes would be too much out; and although the line is by no means required to be perpendicular, yet the shoulder, the hip, the knee, and the foot, should not deviate too far from it, to render a seat perfect. When this is the case, we may be certain the disposition of the thighs and legs is correct, as they will hang down sufficiently straight, and without force or restraint; which can never be the case, unless the body of the rider is placed evenly on the saddle, opening his knees a little, whereby his fork will come lower in the saddle, giving him the appearance, as Shakspeare expresses it, of being "incorpsed and demi-natured with the brave beast."

The position of the foot of the horseman is material both to comfort, safety, and elegance. In the old style of riding, the heels were turned outwards, which, of course, threw the toes inwards, and very near to, as well as parallel with, the shoulders of the horse; but this is all wrong. The toes should be turned a little outward and upward, which the slight opening of the knee induces. No animal, human or brute, can look well, or exert its strength well, with toes turned in, and the position is contrary to every thing approaching to elegance.

The position of the foot in the stirrup, however, varies with the pursuits of the horseman. The soldier always, the rider for pleasure, or on the road, generally, rests on the ball of the foot, with a gentle play of the instep. But the man who rides after hounds, and the jockey when he rides a race, find it necessary to have the foot more home in the stirrup, with the toes turned a little upward, as well as a little outward. The advantages of all this are twofold. First, it gives them more power over their horses, by furnishing them with a more substantial fulcrum; and, secondly, to the man following hounds, it is a great security against the foot being chucked out of the stirrup, by the seat being disturbed in a leap, or from any of those causes which perpetually occur in crossing a country.

Great as has been the alteration for the better in the seat of Englishmen, in general, by increasing the length of the stirrup-leathers, and thereby placing them more properly in the saddle; yet, in the schools of the military this system has been said to have been carried too far, so as to endanger the safety of the rider. Indeed both Hippocrates and Galen speak of a disease which, in their time, was occasioned by long and frequent riding, with the legs hanging down without any support, stirrups then not being in use. How it happened that an advantage so obvious was so long in being made available, is not for us here to inquire; but we consider the support of the stirrup to be the *sine qua non* of the management and services of the saddle horse, for all essential purposes. Nevertheless its most essential use is confined to Great Britain alone, and that is, in enabling the horseman to rise in his saddle to meet the action of the horse in his trot, by which means a pace, otherwise most disagreeable and fatiguing, is rendered nearly the pleasantest of any. So long as the demi-pique saddle was in use, in which the horseman was so deep-seated, and trussed up as to make falling almost impossible; and he rode, as Sir Walter Scott made King James to ride, "a horse keeping his haunches under him, and seldom, even on the most animating occasions of the chase, stretching forward beyond the managed pace of the academy;" pressure on the stirrup might have been dispensed with, but with the saddles of the present day, and the more natural action of the horse, we consider it quite indispensable. It is indeed to the disuse of this practice in France, and other parts of the Continent, where rising in the stirrups is never resorted to even on the hardest trotting horses, that is to be attributed the almost rare occurrence of persons riding any distance, or at a quick rate, for pleasure. To this peculiar system in our horsemanship also are we indebted for our rapid style of posting, as without it post-boys could not endure the fatigue the action of a horse creates, especially in hot weather, over a fifteen miles' stage, at the rate of ten or twelve miles an hour, without a moment's intermission; whereas, by means of it, he performs that task with comparative ease and comfort. The objection to it on the part of foreigners lies in the fancied inelegance, if not indecency, of the motion, which we consider not worthy of an argument; but of this we are certain, that what is called "riding hard," that is, *not* rising in the stirrups, in the trot, nor leaning any weight upon them in the gallop, or canter, must be extremely distressing to horses, and especially to such as carry high weights.

Previously to our describing the various kinds of seat, it is necessary to observe, that how well soever a man may be placed upon his horse, his performance upon him will mainly depend on the use he makes of his hands. It is on this account that old writers on horsemanship have dwelt upon the difficulty of the art, rendered more so, in their time, when the airs of the manège formed part of it. The fact, however, is notorious, that not more than one man in a hundred of those who have been riding horses all their lives, has what is called "a good hand upon his horse," much less a fine one, which falls to the lot of but few. When, however, we consider first, that the hand of the rider is to the horse what the helm is to the ship, that it guides his motions and directs his course; and, secondly, that we have recourse to a severe and cutting instrument, acting upon so sensible and totally unprotected a part, as the *natural* mouth of a horse must be, it is at once apparent, that not only a fine hand, with an easy bit, must be most agreeable, and, at the same time, most serviceable to the horse, in any thing he is called on to perform, but that it constitutes the very essence of fine horsemanship. It has been before observed, that a horse's ear has been figuratively said to lie in his mouth, and no doubt he receives the instruction from his rider chiefly through that medium. How material, then, is it that it should be conveyed to him in a manner in which he is not only most likely to understand it, but in one the least disposed to irritate him? How often have we seen a horse fractious and unpleasant both to his rider and himself, when ridden by an indifferent horseman (allowing him even a good seat) but going placidly and pleasantly when mounted by another with a low and fine hand, which appears to sympathize with all his motions, and all his wishes. It is here that Art becomes the handmaid of Nature; and it is the assistance which it is in the power of a jockey with a fine hand to give a horse, which alone exhibits the superiority of one horse over another *in himself* equally good.

Whence this superiority of hand arises, it is very difficult to determine, particularly as it is so frequently apparent in men possessing equally good seats on their horses. From the well-known fact that it is an accomplishment, which in thousands and ten thousands of cases never can be acquired by the practice and experience of a long life, we may almost consider it to be, like the poets, an *ex re natâ* property in the human composition, and thus sought for in vain by those to whom nature has denied it. That it is intimately connected with the nervous influence of the touch is obvious, from its being the result of the action of the hand and arm; and it is in being delicately alive to every motion of the horse, that the excellence of a good hand consists. That it is associated with the good or bad state of the digestive organs, is proved by the necessity all persons find, who are called upon to excel in horsemanship, of living temperately, and keeping early hours. That it is the greatest security to the horseman, under all circumstances in which he can be placed, is also shewn by the numerous instances we meet with, of some persons being enabled to ride horses over every variety of ground, and in all paces, with security; but which, with others not equally gifted, are constantly getting into scrapes, either by falling on the road, running into fences in the field, bolting out of the course in a race, or falling backwards when rearing, which latter accident arises, in most cases, from a rough, unskilful hand.

Seat on the Road.—Of the various, and too often fatal accidents that occur to horsemen, the majority occur on the road. The reason of this is obvious. They are generally, with the exception of cases of inebriation, the result of horses running away with their riders, and either coming in contact with something in their course, which suddenly stops their career, when either one or both are thrown headlong to the ground. Accidents of this description are very frequently attended with the most serious consequences, and shew the necessity of persons who get on horseback being capable of commanding their horse. Next come accidents from horses falling, which are often attended with fracture of limbs, if not loss of life, chiefly, perhaps, from the hard nature of the ground on which the horse and his rider are thrown; for, if a twentieth part of the falls sportsmen get in the field, their horses so frequently falling upon them, were to occur upon hard ground, the danger in hunting would put a stop to it. Falls from horses starting only happen to persons who have a loose seat, and such should ride none but horses free from that fault. But the greatest safeguard on the road, next to a firm seat, is derived from the hand of the rider, who should never trust himself entirely to his horse, however safe he may consider him. He may tread on a rolling stone; the ground may give way from under him; he may step into a hole; or, by the effect of sudden alarm, he may lose the centre of gravity, and then, in all or either of these cases, the fall is worse, by reason of his getting no assistance from the rider, which he may have looked for, until past recovery, when he comes to the ground with a crash. We therefore recommend persons who ride the road, always to feel their horses' mouths lightly, by which means not only will the proper equilibrium be sustained, and they will be carried better for it; for, observe, a horse with a weight upon his back, and one without a weight upon his back, are by no means in relative positions, but, should a false step be made, the aid of the rider being *instantly* at hand, is nearly certain to recover him. By which rein the mouth should be felt, supposing the bridle to consist of a bit and a bridoon, must depend on the sensibility of it, although by changing the pressure from one to the other, the mouth is kept fresher and more lively than when one only is used, and especially if that one should be the bit. There is a certain, but not a large, proportion of horses, that are rideable for all purposes on the snaffle only, whose mouths are generally kept fresh by the light pressure they receive. These are perfect mouths; but, nevertheless, horses that have them in this perfection, should not be left quite to themselves in any one pace.

Previously to the general use of stage coaches, which are now to be found in abundance upon all roads, road-riding was much more in use than it is at present; and immense distances were travelled over in a day by graziers, horse and cattle dealers, racing jockeys, and others, whose habits of being so much on horseback rendered them superior to fatigue. A hundred miles, from sun-rise to sun-set on the same horse, was no uncommon day's work, and this when the roads were in a very different condition from that in which they now are, abounding in ruts and quarters, so that horses were travelling over half their ground, either on a narrow ridge, between two ruts, or over loose unbroken stones; and these were the days in which really good roadsters fetched large prices, as only horses with very good legs and feet could stand fast work long, or be depended upon as to safety. But all modern feats of men on horseback, or indeed the feats of any other period, on the authenticity of which we can rely, retire into the shade before that performed in the year 1831, by George Osbaldeston, Esq. of Hummanby Hall, Yorkshire, over Newmarket Heath, who rode two hundred miles in nine hours and twenty minutes, winning his Herculean match with forty minutes in hand. As may be supposed, he was not restricted to the number of horses, which consisted of thirteen, then in training on the heath; but he rode one of them, Mr Gulley's Tranby, by Blacklock, sixteen miles, at four four-mile heats. Mr Osbaldeston, also celebrated for his bold and judicious riding to hounds, appeared very little fatigued; and, after the use of the warm bath, and a short repose, joined in the festivities of the evening, and did not retire to rest till an hour after midnight.

An easy seat in the saddle is very important to persons who ride many hours in succession on the road. To accomplish this the following rules should be observed:—To sit well down in the middle of the saddle, with just that length of stirrup leathers that will allow of the fork clearing the pummel of the saddle; for a greater length than this would add to the fatigue of a journey, and lessen the rider's command over his horse. On the other hand, short stirrup leathers create fatigue by contracting the knees, and thereby adding to the exertion of rising to the action of the horse in the trot, which should chiefly proceed from a gentle play of the instep. The body of the rider should incline forwards in the trot, as, by forming a proper counterpoise, the movement of the horse is facilitated; and, above all things, steadiness of seat is required, or the latter will be much incommoded in his action. So distressing, indeed, is a swaggering unsteady seat, that it is a well established, though not a universally known fact, that horses will carry some persons of considerably greater weight than others, long distances on the road, or over a country in hunting, with less fatigue to themselves, solely because they ride them with a firm seat and an easy hand. In a long day's journey on the road, great relief is given to a horse by now and then dismounting from his back, and leading him a few hundred yards; as also by frequent sips of water, particularly if the weather be hot. As to *frequent* baiting of a hackney in a day's journey, the practice is not recommended. In a journey of sixty miles, he should only be stopped once, but then it should be for at least two hours, during one hour of which time he should be shut up in a plentifully littered stall. It is well known that a horse in good condition would perform this distance without hurting him, if he were not baited at all, but we are far from recommending the practice. Short stops, however, on the road are injurious rather than beneficial, and teach horses to hang towards every public-house they pass by, in their journey.

Most horses should be ridden in double reined bridles long distances on the road, and all should be ridden with spurs. Should they flag, or become leg-weary towards the end of a day, the use of the curb may be the means of avoiding falls; and, by the gentle application of the spur, a sort of false, that is, more than natural, action is created, which will have the same beneficial effect. As to the rate at which horses should be put on the road, that is a point so much under the control of circumstances, that no line can be drawn respecting it; but our experience assures us, that if a horse has to perform the distance we have already taken as a fair day's work, namely, sixty miles, under not a very heavy man, he would perform it with more ease to himself, and feel less from it the following day, if he travelled at the rate of seven or eight miles in the hour, than less. In the first place, this rate of speed is no great exertion to a horse of good action, and also in good condition; and, in the next, by performing his day's work in less time than if he travelled slower, he gets sooner to rest, and is, of course, sooner fit to go to work again. Let it, however, be observed, that he should have two hours quiet rest in the middle of the journey, which will enable him to perform it without fatigue. But we do not recommend this rate of travelling, when a much greater extent of ground is before us. If a horse is to be ridden two or three hundred miles or more, he ought not to travel, in the best of weather, more than from thirty to forty miles per day, and he should rest the entire of the fifth day, or he will become leg-weary, hit his legs, or perhaps fall. We are of course alluding to valuable horses, with which extra expense is not to be put into the scale against the risk of injuring them. The earlier, travelling horses, in the summer particularly, start in the morning, the better, that they may get their day's journey over in good time, and be early shut up for the night.

The following good advice to persons riding on the road is very much to the purpose (see *Ency. Brit.* p. 624):—"When you ride a journey, be not so attentive to your horse's nice carriage of himself, as to your encouragement of him, and keeping him in good humour. Raise his head; but if he flags, you may indulge him with bearing a little more upon the bit than you would suffer in an airing. If a horse is lame, tender-footed, or tired, he naturally hangs on his bridle. On a journey, therefore, his mouth will depend greatly on the goodness of his feet. Be very careful, then, about his feet, and not let a farrier spoil them." To this we add, that, as has been already observed, horses often fall on the road, from the state of their shoes being neglected; in journeys, and on hot and dusty roads especially, the feet as well as the shoes demand care. They should be stopped every night with moist clay, or what is better, wetted tow, which, whilst it cools and moistens the foot, acts beneficially, by causing pressure to the sensible sole and the frog.

The Hunting Seat.—Next to that of a jockey, on whose skill in the saddle thousands of pounds may be depending, the seat of the fox-hunter is most essential of any connected with amusement. He must not only be firm in his saddle, to secure himself against falls when his horse is in the act of leaping, but he must unite with a firm and steady seat a light and delicate hand, to enable him to make the most of his horse, as well as to preserve himself as much as possible against danger. His position in the saddle should resemble that which we have recommended for the road, with the exception of the length of his stirrup leathers, and the position of his foot in the stirrup irons. The former, the length of stirrup leather, should depend on the form and action of his horse, as well as the nature of the country he has to ride over. With a horse very well up in his forehand, with his haunches well under him, and going perfectly collected and within himself, his stirrup leathers may be long enough to admit of the knee being very nearly straight, and the foot resting on the ball. But, on the other hand, if his horse be somewhat low in his forehand (which many first-rate hunters are), with very powerful action in his hind-quarters; if ridden in hilly countries, or if at all disposed to be a puller, he will require to be at least two holes shorter in his stirrups; and his foot will be firmer if placed "home" in them, instead of resting on the balls. Above all things, he must acquire a firm, close, and *well-balanced* seat in his saddle, which is not merely necessary in leaping, but in galloping over every description of ground. A swagging seat in the last mentioned act is sufficiently bad to make a great difference to a hunter in a severe chase; but when we picture to ourselves a horse alighting on the ground, after having cleared a high fence, and his rider alighting two or three seconds afterwards in his saddle, so far forward, perhaps, as to fall beyond the pillars of support, or backwards behind the centre of action and the part (just behind the shoulders) which ought to form the junction between the rider and his horse, we can readily imagine how distressing it must be to him, and how much a large fence, so taken, must exhaust him over and above what would be the case if he had had the assistance of a firm hand to support him on alighting; but which, however, with such a seat as we have been describing, no man can possess. The first requisite, then, for a person who follows hounds is the combination of a light hand with a firm seat; and fortunate is it for his horse, as well as for himself, if he possess it to the degree required to constitute a fine horseman, over a country.

But as the science of war cannot be learned perfectly by any thing short of experience in the field, neither can the art of horsemanship, as far as the sportsman is concerned, be learned perfectly in the riding-school or the academy. If our own observation did not confirm this fact, it would appear evident, from the variety of situations in which the man following hounds may be placed, in one individual run; and we will endeavour to enumerate them. First, there is galloping at very nearly full speed, not over turf as smooth as a carpeted floor, and with nothing beyond a daisy's head to come in contact with the horse's feet, but (*cursu undoso*) over every description and every variety of ground; over the high ridge and across the deep furrow; over ground studded with ant-hills, which, unlike the mole-hill, are often as hard as if they had been baked in an oven; over stones and flints, the latter so sharp as frequently to sever the sinews of a horse's leg so completely as to cause his toe to turn upwards, when his throat must be cut on the spot; over grips covered by weeds, and thus, if visible to the horseman, too often invisible to his horse; over deep under-drains, with rotten coverings, which frequently give way, and let in a horse nearly to his shoulders; down steep hills, stony lanes, through deep sloughs and treacherous bogs; and all this very frequently on infirm legs, as those of hunters which have been long in work are very apt to be.

Next come the "fences," as all obstacles to the follower of hounds are now technically termed; and let us just see of what they are composed. There is the new and stiff gate, with always five, and sometimes six bars, and each bar, perhaps, as firm against the force or weight of a horse and his rider as if it were made of wrought iron. Then there is the nobleman or gentleman's park-paling, full six feet high, and too often a turnpike road on the other side to alight on. The stiff four-barred stile, generally to be taken from a narrow and slippery foot-path, and not unfrequently on the declivity of a hill. The double post and rail fence, as it is called, too much to be cleared at one leap, in which case the horse has to leap the second rails from the top of a narrow bank, and sometimes from out of a ditch which is cut between them. Every now and then, in the rich grazing countries, which are far the best for hunting, and in which hounds run faster than in others, there is the ox-fence, which may thus be described: If taken from one side of it, there is, first, a ditch, then a thick and strong black-thorn hedge, and about two yards beyond it, on the landing side, is a very strong rail, placed to prevent feeding bullocks from running into the hedge, to avoid the œstrum, or gadfly, in the summer. This fence, covering a great space of ground, must be taken at once, or not at all, from either side on which it is approached. In these countries, from the goodness of the land, the black thorn attains great strength; but in places where it happens to become weak, instead of the ox fence, four strong rails are put, which, in addition to the ditch, makes also rather an awful fence; at least, if a horse do not clear it, he must fall, as the rails very rarely will give way. Some of these hedges being impracticable, from their thickness, the sportsman makes his way to one corner of the field, where he finds a flight of very high and strong rails, but without a ditch, and every now and then a sheep-fold. The former is somewhat of a more severe fence than it appears to be, owing to the ground on each side of it being either poached by cattle, or, what is worse, rendered slippery by sheep, which are driven into the corner to be examined by the shepherd, in the case of there not being a sheep-fold in the field. The sheep-fold, or sheep-pen, as it is called in Leicestershire, is a still more serious undertaking. To get into it, the horse must leap four strong bars, about the average height of gates, and then, with a very short space to turn himself round in, must do the same thing to get out of it. Next comes the brook, from twelve to twenty feet in width, often bank-full, and sometimes overflowing its banks, which are often hollow, and generally rotten. In most of our best countries, few runs of extent take place without a brook, or brooks, being to be crossed; and no description of obstacle to which the sportsman is subject in crossing a country is the cause of so many disasters.

In what are termed the Provincial Hunting Countries, in contradistinction to Leicestershire, and the other chiefly grazing countries, timber, with the exception of stiles, is not so frequent, nor is the ox-fence to be seen at all; but there is comparatively more fencing, though chiefly hedges and ditches. In many of these, Dorsetshire in particular, the fences are generally what is termed double; that is, there is a ditch on each side of the hedge, which it requires a horse to be prepared for, by receiving, if not his education, a good deal of instruction in the country. In other parts of England, Cheshire and Lancashire, for example, we find fences that require an apprenticeship. They consist of a hedge and ditch, not of large dimensions, but in consequence of the former being planted on a cop, or bank, a horse must land himself on the cop before he can get his footing to clear the fence, provided the hedge be on the rising side. Were he to spring at it from the level of the field, and clear the bank, together with the hedge and ditch, the exertion would be so great as soon to exhaust his powers. Those fences require horses very active and ready with their hinder legs, and also riders with good hands. In all strong plough-countries, as our fine loams and clays are termed by sportsmen, hedges with ditches (for the most part only one ditch) prevail. For height and width they are not equal, by much, to those of the grazing districts, but circumstances render them equally difficult and trying to the skill of a horseman, and the judgment of his horse, and oftentimes still more so. In the former, although the fence is large (brooks excepted) the ground on the rising side is almost always sound and firm; whereas in deep plough-countries it is generally soft, and often, what is worse, it is sticky. Neither is this all. It very often happens that the headland of a field is ploughed to within a foot or two of the ditch, when a small ridge, or "balk," as it is termed in some districts, is left to prevent the soil of the field washing into the ditch. This ridge is often very perplexing to the horseman. He must either put his horse at the fence so as to clear all at once, or he must let him take his footing from off this narrow ridge, which, if his head be not in a very good place, and his rider's hand an indifferent one, makes even a small fence dangerous. The objection to a ploughed country also holds good as regards the other, the landing side of the fence. In the grass countries, a horse alights on turf sufficiently elastic to break the concussion from the weight of himself and his rider, but seldom soft enough to sink him below his hoofs. On the other hand, in the ploughed districts, he is perpetually alighting in fallowed ground, or in that sown with wheat or other corn, which, particularly after a severe frost, is so far from being firm enough to bear his weight, that it sinks him nearly to the knees. This is very distressing, especially to a horse which carries a heavy man; and here the skill of the rider is shewn in his preventing his jumping at fences of this description, higher or farther than is absolutely necessary to clear them. To a man who follows hounds, indeed, this art of handing his horse easily over fences, is one of the very highest value; and to the possession of it, to perfection, is to be attributed the extraordinary performance of hunters under some of our heaviest sportsmen, such as Mr Edge and his brother, Mr Richard Gurney, Sir Bellingham Graham, Mr Maxse, Lord Alvanley, and others, in fast runs of an hour or more, over strongly inclosed countries.

Walls are, we believe, the only fence met with in Great Britain which we have as yet left unnoticed. They are of two descriptions, namely, fast, by means of mortar, and loose, being built without mortar. The first do not often come in the way of the sportsman; and it is well that they do not, for, in the event of a horse striking them, they do not yield to his weight. The last, the loose walls, particularly those met with in Gloucestershire and Oxfordshire, are the least dangerous fences he can ride at; for, unless his horse be blown, or he is himself a very powerless horseman, they seldom resist him sufficiently to throw him down. Their height varies from three to five feet; but as there never is a ditch on either side of them, and the ground is generally firm in the parts of those counties which are inclosed with walls; those even of the last-mentioned height may be taken with safety by a good horseman, on a horse that is accustomed to them, and is not distressed at the time by the pace; for, as "*it is the pace that kills*," so is it the pace that causes falls.

The following directions may be serviceable to a young beginner in the hunting field:—When hounds find and go away, place yourself well down in your saddle, on your fork, or twist, and dont be standing up in your stirrups (as formerly was the fashion, and the cause of many a dislocated neck), sticking out your rump as if it did not belong to you. Let your knee be not very far from straight, with your foot well out in front of it, and feeling in the stirrup as if it formed a sufficient fulcrum for your bodily strength to act upon, in the assistance your horse may require from you. Be assured that the military seat, with the very long stirrup leathers, will not do here, however graceful it may appear on a parade. There must be a kind of *obstando* power in the rider, to act against the preponderance of his horse, particularly at what are called drop-leaps, in very deep ground; or, in case of his making a blunder, or getting into false ground, in his gallop. Having got well away with the pack, keep your head up, with your reins in the left hand, and your whip in your right, held perpendicularly upwards, with the thong falling loosely through your hand, when it will be ready for all purposes. Cast your eye forward, to take a view of the country, and then on the body of the hounds, to satisfy yourself that they are well settled to the chase. And now comes the young fox-hunter's trial. *You must neither take liberties with the hounds, nor with your horse.* Ride wide of, that is, on the left, or on the right of, the former, turning as you see them turn, and never find yourself exactly behind them, on their line; and no matter how perfect may be the latter, never trust him to himself, nor upset him by going too fast for him, or, in other words, over-marking him for pace. However good his mouth, never ride him in chase with quite a slack rein, for, independently of your own safety, it is not giving him a fair chance. He requires your support, and he should have it.

In riding to hounds, there is much to be gained by what is termed picking out your country. Avoid going straight across land highly ridged, and, consequently, deeply furrowed, if possible to avoid it, but rather take your line diagonally. If the furrows are very deep and holding, make for the side, or the head-land, where, of course, it is comparatively level ground. Even if it takes you a little out of your line, you will find your advantage in this, for you may increase your rate of going, and that with ease to your horse, more than equal to the extra distance you have to go. If your horse appear somewhat distressed, it is on a head-land, or still more on a long side-land, that you have a good opportunity of recovering him; and here you may have recourse to the old-fashioned style of riding a hunter. You may stand up in your stirrups, catching fast hold of your horse's head, and pulling him well together, when you will find, that, without slackening his pace, he has recovered his wind and can go on. Avoid deep ground as much as possible; but when in it, keep a good pull on your horse, and by no means attempt to go so fast over it, as you have been going over that which was sound. After Christmas, turnip fields should be skirted if possible; for, by reason of the many ploughings they receive at seed-time, the land sown with turnips becomes so loose and porous after severe frost, that it cannot carry a horse. Also avoid *crossing* fallows, or land sown with wheat. If obliged to go athwart them, get on the head-land; or if you ride straight down them, choose the wettest furrow you can see. It is sure to have the firmest bottom, which is proved by the water standing in it.

As no man can say where a fox-chase will end, have an eye to your horse, and endeavour to give him all the advantages in his favour that the country and the pace will admit of. Next to a judicious choice of your ground, is quickness in turning with hounds, as the difference between riding inside and outside of them, in their turns (be it remembered hounds very seldom run straight) is very considerable indeed; and to a certain degree corresponds with what is called "the whip-hand" in a race. Again, if you wish to stand well with the master of the pack, and to obtain the character of a sportsman, observe the following rules:—Never press upon hounds, even in chase. When they have lost the chase, in other words, when they are at fault, pull up your horse and keep wide of them; and, in the words of a celebrated old sportsman, "*always anticipate a check.*"

Never, for the sake of displaying your horsemanship, or your horse, take an unnecessary leap when hounds are running, nor a large one when a smaller is in your view, unless the latter take you too much out of your line, or for a reason which we shall presently give. If your horse is a good timber leaper, and not blown, prefer a moderate timber fence to a rough, and blind hedge-and-ditch fence, as less likely to give you a fall, neither will it take so much out of your horse. But when your horse becomes distressed, avoid timber, for if he do not clear it, he will give you a worse fall in that state than if he were quite fresh. A blown horse falls nearly as heavy as a dead one. There is, however, another precaution to be observed with horses a good deal beaten by the pace. Have an eye, then, rather to the nature of the ground on which it is placed, than to the size of the fence; that is, prefer a good-sized fence, where you see firm ground for your horse to spring from, to a small one where it is soft and sticky. Moreover, a distressed horse will often rise at a fence of some height and appearance, whereas he will run into, or, at all events, endeavour to scramble through, a small one. If you decide upon the smaller place, let him go gently at it, as he will be less likely to give you a fall; at all events, he may not give you so bad a one as if you went fast up to it. Some horses get out of scrapes better than others; but it is as well not to give them an opportunity of shewing their prowess in such matters.

A chief requisite to a good rider across a country is, courage, one of the most common qualities of human nature; and another is, coolness. No man, when flurried, can do any one thing well; but when we consider the variety of objects that the sportsman, following hounds, has to attract his notice, and the many obstacles he may have to encounter, it is evident that, according to the old adage, "he must have all his wits about him." The perfection of fine horsemanship in the hunting-field, then, is in a man riding well up to hounds, when going their best pace, over a stiff country, and yet appearing to be quite at his ease, and his horse, as it were, sympathising with him in his calmness. Such a man (and there are some such in every hunt, but not many) is capable of taking every advantage that can be taken of country, hounds, and all obstacles which appear to oppose him in his career. Another signal advantage to the sportsman also arises from his coolness in these moments of no small mental, as well as bodily, excitement and exertion. He is able to observe the beautiful working of the hounds, which is displayed to advantage with a burning scent; and he enjoys it the more, in consequence of the superiority of his horsemanship having placed him in a situation where he is not molested by the crowd.

Horsemanship.

The greater part of mankind, it is true, are endowed with a capacity for performing, and, to a certain degree, excelling in, the various exercises which have been invented for our amusement; but we have reason to believe, that out of the vast numbers of persons who attempt the apparently simple art of horsemanship, particularly that part of it which we have now been speaking of, there are fewer who arrive at perfection in it, than in any other with which we are acquainted. Luckily, however, for sportsmen, it is not in horsemanship as in the fine arts, which admit of no difference between distinguished success and absolute failure; and it is certain that there are more good and spirited riders to hounds at the present day, than were ever known since fox-hunting, as now practised, begun. And Englishmen may be proud of this; for although amongst the classical glories of antiquity, we hear nothing of leaping five-barred gates, twenty feet drains, and six-feet walls, after hounds, yet a daring horseman always found honour. Alexander the Great first signalized himself by subduing an unruly horse, which no man but himself dared to mount; and his celebrated general, Eumenes, was first noticed by Philip his father, on account of his skill in horsemanship and all public exercises. Neither are there wanting parallel cases in our own country, in which titles and honours have been conferred upon persons who might never have been known to him who conferred them, but for their possessing similar accomplishments.

Although speed in the hunter is now absolutely necessary, from the much increased rate of hounds, yet it is equally necessary, in most of our hunting countries, that he should be a perfect fencer as well, and that his rider should be an accurate judge of the extent of his fencing powers. Thus it often happens that horses, not equal in speed to others, get quicker over a stifly-inclosed country than they do, because, by the means of their superior fencing, they are able to cut off angles and go straighter. In fact, there are frequent instances of one individual sportsman beating every other in the field, and being alone throughout a run, merely by clearing a great fence in the direct line of the hounds at starting; in avoiding which, so much ground had been lost by the rest of the field, that it could not be recovered by them until the chase was ended.

The effect of the exertion of leaping, in horses, is pretty accurately ascertained by the observation and experience of sportsmen; but some rather curious facts are drawn from them. A very large fence, as has been before observed, exhausts a horse, or, in the language of the field, "takes a good deal out of him;" nevertheless, a hunter becomes sooner distressed over quite an open country, when the pace is very severe, than he does over an inclosed one, provided the fences are not very large indeed. This is accounted for in two ways: First, fences check the speed of hounds, and consequently the speed of horses. Secondly, the mere act of pulling or gathering a horse together, to shorten his stride previously to his taking his leap, is a very great relief to his wind, as we know from the effect a good pull at his bridle, towards the end of his course, has on that of the race-horse. At several kinds of fences, likewise, it is necessary that he should be pulled up nearly, if not quite, into a walk, to enable him to take them with safety, such as fences by the sides of trees, hedges with ditches on each side of them, particularly if they are what is termed "blind:" in short, all places known in the hunting vocabulary as cramped places, as well as now and then a timber fence, which must be taken nearly at a stand. And it was the old system of taking all upright fences, such as gates, rails, stiles, and hedges without ditches, at a stand, that enabled the low-bred hunter of the early part and middle of the last century to live with hounds as well as he did live with them. The very short time that it takes for a horse to recover his wind, to a certain extent, might be proved by a reference to stage-coach work. Previously to the perfect manner in which it is now performed, and the superior condition of the cattle, from their owners having at length found out how to feed them, it was not unusual for a coachman to have a high blower, as a thick or bad winded horse is called on the road, in his team, which might scarcely be able to keep time. If he found him distressed, he would pull up his coach on the top of a hill, and draw back the distressed horse from his collar. But how long would he keep him in this position? Why, not many seconds, before he would be sufficiently relieved to proceed. Thus the country of all others which puts the physical powers of horses to the greatest test in following hounds, is one which is hilly, and totally without fences, of which the Sussex South Downs, in the neighbourhood of Brighton, may be taken as a sample. Nothing but a thorough-bred horse, and a good one too, can live quite alongside hounds, going their very best pace, more than half an hour over such a country as this, and very few can do even so much, if they carry more than average weight. The open ploughed countries, such as great part of Wiltshire and Hampshire, are for the same reason very distressing to horses, and require them to have a great share of blood; but hounds do not, neither can they, run so fast over ploughed ground, as over old, or maiden turf, which the Sussex Downs are clothed with. In the first place, the scent is seldom so good; secondly, the ground is not only not elastic, which the other is, but it impedes the progress of hounds from two other causes; its surface is less even, and the soil of all ploughed land sticks more or less to the feet of hounds; or, in the language of the huntsman, it "carries" invariably after a slight frost on the previous night.

We now resume our advice to the young foxhunting horseman: It is the practice of all first-rate horsemen over a country to ride slowly at the majority of fences. For example, if the ditch be on the rising side, you may cause your horse to put his feet into it before he rises at the hedge, if you hurry him at it. Should the ditch be on the landing side, the case is somewhat altered, as the pace you ride at must be regulated by its width. If you have reason to believe it is of moderate width, do not go fast at the fence, because it will cause your horse to leap further than he needs to leap, and of course help to exhaust him. But if, when within a few yards of the hedge, going slowly at it, you perceive the ditch is a broad one, "put in some powder," as the modern sporting term is; that is, urge your horse by the hand and spur, and he will be aware of what you wish him to do, namely, to extend himself so as to clear a wide space of ground. If the ground on the landing side be lower than that on the rising side, causing what is called "a drop leap," or even if the ground be not lower, but soft or boggy, your horse will look for assistance from you on alighting, which you should give him by throwing your body back, having at the same time a resisting power from your stirrups. But another precaution is necessary when the ditch is on the rising side, or indeed with all fences except those (as will be hereafter named) which require to be ridden quickly at. This is, to fore-shorten the horse's stroke so as to enable him to gather himself together for the spring, or he may misjudge his distance, and get too near to his fence to rise at it. In fact, to judge accurately of the distance from the fence, at which the spring should be taken, is a great accomplishment in a man and a horse. In the former, it is the result of experience and a quick eye; with the latter, it is in great measure dependent on temper; and consequently violent horses, "rushing fencers," as they are termed, never perfectly acquire it. It is a serious fault in a horse to take his spring sooner than he need take it; and perfect fencers go close up to their fences before they rise at them, particularly to hedges when the ditches are on the landing side. Horses, however, of hasty tempers, particularly well-bred ones, with great jumping powers, cannot always be made to do so. Neither will they save themselves by walking into, or pushing through, places which do not require to be jumped; on the contrary, many otherwise excellent hunters will scarcely suffer a brier to touch their legs. A good bridle-hand here comes into play, more especially with horses who are rather difficult to handle, either from too fine a mouth, or a loose, ill-formed neck. It is difficult, however, to offer instruction here, as there ought to be an absolute interchange of feeling between the instructor and the instructed, to render them intelligible to each other; but we will endeavour to make ourselves understood:—When you approach a fence with a horse of this description, you should leave him as much to himself as you find it prudent to do, particularly when within a few yards of it. If you are obliged to check his speed, do so with as light a hand as possible; and if he shews a dislike to be much checked, by throwing up his head, or otherwise, drop your hand to him, and let him go. He has by this time most probably measured the fence by his eye, and it may not be safe to interfere with him.

Double fences, particularly with a horse not quite perfect in his mouth, and the setting on of his head, try the hand of the horseman. The first part of the fence, usually a ditch, may be cleared without any difficulty, and so may the second, if visible; but it often happens that neither horse nor rider is prepared for the second. Here it is that, in our opinion, lifting a horse is to be recommended, and in very few cases besides. Our objection to it arises from the horse being led to expect it; and if he do not get it at the critical moment, it may mislead him. In fact, it requires a hand nicer than common to make a practice of lifting a horse at his fences. Nevertheless, in the instance we have alluded to, the unforeseen ditch, it is useful; as also towards the end of a run, when a horse, from distress, is given to be slovenly at his fences, if not disposed to run into them. In leaping timber fences, we consider the attempt to lift a hunter dangerous; for a horse becomes a good timber-leaper from confidence; and if he finds he is to wait, as it were, for your pleasure for him to rise at a gate or a stile, he will be very apt to make mistakes.

We have already observed, that timber fences are the most dangerous of any, by reason of their general strength; if a horse strikes them with his fore-legs, or gets across them, as it were, by not being able to bring his hinder-quarters clear of them, they are nearly certain to cause him to fall. And he falls from timber in a form more dangerous to his rider than when he merely stumbles and eventually falls, by putting his feet into a ditch. In the latter case, his fore-quarters come to the ground first; and by breaking the force of the fall, the rider has time to roll away from him before he himself rolls over, should the violence of the fall cause him to do so. In the former, if the timber be strong enough firmly to resist the weight and force of a horse that strikes it with his fore-legs, especially if above the knees, the first part of his body which comes to the ground is either his back or his rump. Should the rider then not be thrown clear of him, he must be made of hard materials if no bones are broken, or some serious injury sustained. All this, then, enforces the advice we have already given, of avoiding strong timber with horses not perfect at leaping it, as much as may be compatible with keeping your place with hounds; and still more so with horses, how perfect soever they may be at it, that are blown, or very much distressed. It likewise induces us to point out the best and safest method of riding at this description of fence.

Never ride a horse fast at a timber fence, unless it be a low one, with something wide to be cleared on the landing side. If a man or a boy is seen exercising himself in jumping heighth, you do not see him run quickly at it, nor does he run over any considerable space of ground before he springs. On the contrary, he only takes a few steps, and those at a moderate rate. Never, then, ride your hunter fast at gates, stiles, &c. unless in the one case alluded to. Mr Thomas Assheton Smith, perhaps more celebrated for his horsemanship in the hunting field than any other person of the present age, and who was for many years at the head of the Quorndon (Leicestershire) Hunt, never rode fast at any fences, brooks excepted, and then only under circumstances which will be explained when we treat on that part of our subject. When riding at timber, however, take a firm hold of your horse's head, chiefly by the aid of the bridoon, if his mouth is good enough for it; and let him understand, by assuming an air of resolution on your part, that you not only mean him to leap it, and that you will not suffer him to turn his tail to it, but that it is something at which his best energies will be required of him. But, above all things, do not interfere with his stroke or stride, unless absolutely called upon by some peculiarity of the ground, such as a grip on the headland, or a small ditch on the rising side. A horse making up his mind to leap a timber fence, will of his own accord regulate that matter, and gradually gather himself together on his haunches, previous to being required to take his spring. He will also, if you let him, often make choice of his pace at which he goes up to a gate, &c. It is true the deer can clear a greater height in its trot than in any other pace; but a horse prefers the very slow gallop, or canter, when thus called upon to exert himself; for if he do trot to any upright fence, we generally see him break into a canter in the last few yards. As the fulcrum for the spring comes from behind, the canter is the most natural pace, the haunches being at this time more under him.

The same instructions to the horseman hold good with regard to stone walls as to timber fences, at least to those met with in England, which are loose, and without ditches. But in several parts of Scotland the case is different, as the sportsman very frequently has to encounter walls with ditches on one side or the other of them. In consequence of their being placed at some distance from the wall, to prevent the water which runs down them undermining the foundation of it, there is frequently room, when the ditch is on the rising side, for a horse to leap the ditch, and take a second spring from the intermediate space, and so clear the wall. But when he has to leap the wall, with the ditch on the landing side, it becomes a very difficult fence, and must be ridden at with judgment. If the ditch be not too far from the wall, to come within the stretch of a hunter, he should be ridden quickly at it, and well roused by the rider, to make him extend himself sufficiently; but if it be too far, he should be put very slowly at the wall, so as to enable him to drop, with his hinder legs at least, on the intermediate space, and from thence spring over the ditch. This fence is very trying to horses not accustomed to it; and with those which are, one fact becomes apparent, namely, that the mere holding the reins of a bridle does not constitute what is called "a hand" on a horse. A workman with a "finger" is wanted here.

In riding at every description of timber your seat as well as your hand requires attention. You have already been told on what part of your horse you ought to sit, namely, in the middle of your saddle, which should be placed close to the shoulder bones, when your seat will be most secure, from its being just in the centre of motion when your horse springs at his fence; as, in the rising and falling of a board placed in equilibrio, the centre will be most at rest. Your true seat, indeed, will be found nearly in that part of your saddle into which your body would naturally slide if you mounted without stirrups. But other security than this is required, to insure safety over very high fences. It is not the horse's rising that tries the rider's seat; the lash of his hinder legs is what ought to be chiefly guarded against, and is best done by the body's being greatly inclined backward. Grasp the saddle lightly with the hollow, or inner part of your thighs, but let there be no stiffness in any part, of the person at this time, particularly in the loins, which should be as pliant as those of a coachman on his box, when travelling over a rough road. A stiff seat cannot be a secure one, because it offers resistance to the violent motions of the horse, which is clearly illustrated by the cricket-player. Were he to hold his hand firm and fixed when he catches a ball struck with great force, his hand or arm would be broken by the resistance; but by yielding his hand gradually, and for a certain distance, to the motion of the ball, by a due mixture of opposition and obedience, he catches it without sustaining injury. Thus it is in the saddle. A good horseman recovers his poise, by giving some way to the motion, whereas a bad one is flung from his seat, by endeavouring to be fixed in it. In old times, when hunters were trained to leap all upright fences standing, these precautions were still more necessary, because the effect of the lash of the hinder quarters was more sudden and violent, in consequence of the horse being so close to his fence, that he rose perpendicularly at it, and not with the lengthened sweep of a flying leap.

Although Virgil, in his third Georgic, speaks of not suffering the brood mare to leap fences (*non saltu superare viam*), we find nothing on this subject in the classics, to induce us to believe that the ancients, although they hunted, were given to ride over fences. Here they sustained a loss; for we know few more delightful sensations, than that experienced in the act of riding a fine flying leaper over a high and broad fence. Nothing within the power of man approaches so nearly to the act of flying; and it is astonishing what a great space of ground has been covered at one leap by horses following hounds, or, at other times, with first-rate horsemen on their backs, who alone have the power of making them extend themselves to the utmost; and particularly when the ground, on the rising side, is sound, and somewhat in favour of the horse. In the grand Leicestershire steeple chase of 1829, a grey horse, called "The King of the Valley," the property of Mr Maxse, and ridden by the justly celebrated Mr Richard Christian of Melton Mowbray, cleared the previously-unheard-of space of eleven yards, or thirty-three feet. Yet, after all, the most extraordinary fact relating to the act of leaping in horses, is the power they have of extending themselves by a second spring, as it were, when, on being suspended in the air, they perceive something on the further side of a fence, for which they were not prepared. That they occasionally do this under good horsemen, all good horsemen of experience can vouch for; but whence the fulcrum is derived, it would be difficult to determine. All horses which have been in Leicestershire, and other countries where the fences are large and wide, become more or less accomplished in the act of throwing themselves forward, as well as springing upward, causing a very pleasant sensation in the rider, as well as an assurance that he is not likely to drop short into the ditch or brook.

We have already said, that brooks stop a field more than any other description of fence, and for the following reasons: Very few men, and still fewer horses, like jumping brooks. In the first place, as concern the rider, they are very apt to injure his horse by a strain, or a bad over-reach; secondly, water is deceiving as to the extent of it; thirdly, a wide brook takes much out of a horse; and, lastly, the banks often give way, after the horse supposes he has landed himself; and although it is easy for him to get into a brook, it is often very difficult for him to get out of one. Few horses become very good water-jumpers, unless they have been hunted a good deal in countries where brooks abound, and also have been fortunate in not getting into one of them in their noviciate. For this reason, it is a hazardous experiment to give a large price for a hunter, how high-soever may be his character, that has been only hunted in counties like Hampshire or parts of Wiltshire, where there are no brooks but such as, from the soundness of their bottoms, horses may walk through. We have already stated the most likely way to make a young horse a good brook-jumper; a very superior accomplishment in a hunter, and chiefly to be attained by his acquiring confidence.

There is one other untoward circumstance attending leaping brooks with hounds. They are, for the most part, met with in the middle of a field, and it often happens that, until the horseman arrives on the very brink of them, he cannot form a correct estimate of their nature or extent. They also vary much in both these respects, we mean in the soundness or unsoundness of their banks, and in their width, in the space of a few yards; so that it is in some measure a matter of chance whether you have to leap a wide brook or a narrow one. But then, it may be said, you can always satisfy yourself on these points. True; you may do so: but what would too often be the consequence? Why, if you shew your horse a brook before you ride him at it, it would too frequently happen that he would not have it at all; add to which, whilst you were doing this, on a good scenting day, the hounds would get a long way a-head of you. Besides, the *vis vivida*, or momentum of the horse's gallop, so necessary to get him well over wide brooks with rotten banks, is wanted, but in this case would to a certain extent be lost; and if he is once pulled up, and turned around, it is not so readily acquired again, as he is always more or less alarmed, after having got a sight of what he is going to encounter. Wide brooks, then, with uncertain banks, are the only fences which should be ridden very fast at; for, exclusive of the advantage the horse gets from the impetus derived from the speed, should he fall on the other side from false ground, he will generally save himself from dropping backwards into the brook, an object of no small importance to him, as also to his rider. There are, however, exceptions to the rule of riding *fast* at brooks. When they are not wide, and the banks are sound, it takes less out of a horse to put him at a moderate rate at them. Neither should he be ridden quickly at them when they overflow their banks, as it will then require all his circumspection and care to know when, or where, to spring from, to cover them. In fact, overflown brooks are rather formidable obstacles; but (a fine trial of hand) numerous instances do occur in the course of a season, where they are leaped when in that state by some of the field, but not by many.

Although, when the sportsman rides over a very wide brook, or any other fence which requires much ground to be covered, he has a certain hold by his bridle; yet, as may be supposed, it is very unequal to the weight of his own body, increased by the resistance of the air. How happens it, then, that his horse does not leap from under him? or, at least, how is it that, when the horse alights, the rider alights in the very same spot in the saddle on which he sat when his horse rose at it? The fact is, his body so far partakes of the speed of his horse, and increases in common with it, that, with very little assistance from his bridle-reins, he keeps himself in his proper place. If it were not so, what would become of the rider in the circus, who leaps directly upward, through a hoop perhaps, or over his whip, whilst his horse is going at considerable speed? He would, of course, alight upon the ground, perpendicularly, under the point at which he sprang from his saddle. It is evident, however, that on leaving the saddle, the body of the rider has equal velocity with that of the horse; and the spring, which he takes perpendicularly upward, in no degree diminishes this velocity; so that, while he is ascending from the saddle, he is still advancing with the same speed as his horse, and continues so advancing until his return to the saddle. In this case, the body of the rider describes the diagonal of a parallelogram; one side of which is in the direction of the horse's motion, and the other perpendicularly upward, in the direction in which he makes the leap. From these facts, these striking instances of the composition of motion, then, may the advantages of good, and the disadvantages of bad, horsemanship be appreciated; and as it appears that the motions of the rider and his horse are so intimately connected and in unison with each other (for were the circus rider to project his body forward, in his leap through the hoop, as he would do if it were on the ground, he would alight on his horse's head or neck, or perhaps before his head, for he would then advance forward more rapidly than his horse), the importance of a steady seat and a good hand is apparent, and accounts for some men crossing a country on middling horses, quicker and better than others do upon really good ones.

Having spoken of overflown brooks, and being aware of the many fatal disasters that have occurred to sportsmen in water, and the narrow escapes of drowning from crossing flooded rivers, by others, within the last twenty years, we are surprised that the exercise of swimming horses, in the summer months, is not more generally resorted to. It was practised by the ancients; for we find Alexander swimming the Granicus with thirteen troops of horse. But the horses should be practised in swimming as well as their riders, or it would not avail the sportsman so much, as we know some horses are very much alarmed when they lose their legs in water, and often turn themselves over. That the act of swimming on horses is a most simple and safe one to those who practise it, may be proved at any of our watering places in the summer, where boys swim them out to sea, two at a time, changing their seats from one to another with the greatest ease. We observe they generally lean their body forwards, so that the water gets under it, and partly floats it, interfering as little as possible with the horse's mouth; at all events, never touching the curb rein. When the sportsman or the traveller has occasion, or is accidentally called upon, to swim his horse through deep water, and the banks will admit of it, he should enter it as gradually as possible, as not only will his horse be less alarmed at the loss of his footing, but less liable to turn himself over in it. Thus in fording a brook too wide to leap, and with a soft bottom, a horse should be ridden *very slowly* into it, which will enable him to get his hinder legs well under his body before he makes his spring to ascend the opposite bank; which he cannot do if he enter the brook quickly.

As the young sportsman may be induced to "make his own horses," as the term is for qualifying them for the appellation of hunters, it may not be amiss to offer him a few words of advice. Be careful, the first season, how you ride them at very cramped places, especially where there is timber, for they cannot be expected to be *au fait* at such things; and many of the worst falls that some of our hard-riding sportsmen have experienced, have been from expecting young horses to do what old, or at least experienced ones, only can do. Avoid also taking the lead with hounds, especially if they run hard, with a young horse, for it may cause him to refuse a big fence which he might have followed another horse over, and thus become a refuser ever afterwards. Although horses do not understand languages, they understand the arbitrary signs of their masters or riders; and if a young hunter makes a slovenly mistake with you at a fence, he should be corrected with either spur or whip, and also *by the voice*. The merely calling out to him, or exclaiming, "For shame—what are you about, eh!" accompanied by a slight stroke of the whip, has often a very good effect, and will be visible at the next fence, when he will be more careful where he puts his feet, and take a greater spring. A horse knows his errors; also, when he is corrected, and when cherished, each of which he should be subject to in their turns; but as, according to the old adage, a coward and a madman are equally unfit to be horsemen, the correction of a young hunter should not be severe. Nothing would be more likely to make him what is called a "rushing," and consequently an unsafe fencer for the rest of his life, than beating him *severely*, for any trifling faults he may commit in the field. Martingals on hunters are now generally condemned; but, in our opinion, more generally than they deserve to be, particularly during the first season of a young horse, as a long martingal serves to steady his head, if he is a little impetuous, and saves him many falls, which, putting his rider out of the question, are injurious to him, as all horses become large fencers, in a great measure, by having confidence in themselves, which falls must necessarily shake. All horses, indeed, whose necks are weak and loose, may be ridden with advantage by the aid of a martingal on the bridoon rein, *the rings coming quite up to their jaws*, when it cannot interfere with their galloping or their leaping. We remember the time, indeed, when the first sportsmen and hardest riders of the day, were never seen without a long martingal, *on horses whose heads were not quite in the right place*, and be it remembered that nineteen out of twenty race-horses are ridden in martingals. Nevertheless we would avoid the use of them when not absolutely necessary, as the more liberty a hunter has, the more likely he is to recover himself when in difficulty.

The perfect command of a horse in the hunting field is in nothing more essential than in passing through half-opened gates, and many have been the bad accidents that have arisen from the want of it, horses being often stuck fast between the gate and the post, to the no small injury to their rider's legs or knees. Indeed the being handy in opening a gate, is no trifling accomplishment in a hunter; and here a few lessons in the school may be of advantage to him. He would there be taught to obey the leg as well as the hand; and, by a slight touch of the spur, would throw his haunches round to the left, on his rider unfastening the latch with his right hand, and thus enable him to throw the gate behind him, and pass through it. This has reference to gates that open *towards* the horseman; such as open *from* him, require not the horse's aid. But it often happens when a horse is blown, or beat, that unless he have a very good mouth, he will hang upon a gate, and nearly prevent his rider from opening it at all. One precaution, however, should always be taken with gates: the rider should never trust to catching the topmost bar, or what is called the head of the gate, but should pass his hand inside of it, when he will be certain to come in contact with some part of it.

Falls.—There is a proverb, and a true one, which says, "He that will venture nothing, must not get on horseback." All men, however, who ride a-hunting are subject to falls, but those who ride near to hounds, or "hard," as the term is, seldom escape without having several in the course of a season. It is well, then, that the young sportsman should know, that there is an art in falling, as well as in preventing falls. This consists in getting clear of the horse as soon as possible, which a man in the habit of falling has a better chance to do than one who runs less risk of it, having greater self-possession at the moment. Next to a horse coming neck and croup over a high timber fence, a fall in galloping at full speed is most dangerous, and apt to dislocate the neck, by the head coming first to the ground; and from the velocity of the fall, the rider has no time for precautions. However, even in this case he should endeavour to put out one hand, if not both, to break the force of the fall, as well as to act in resistance to his head coming first to the ground, and receiving the whole force of the concussion. By so doing, it is true, the collar-bone stands a great chance of being fractured; but that is an accident merely of temporary inconvenience, and unattended with danger, whereas a dislocated neck is very rarely reduced. But it is a curious fact, that there are fewer instances of broken necks in the field in the present age, than there were nearly a century ago, notwithstanding that for one man who rode a-hunting then, there are fifty now; and the pace of hounds, as well as style of riding, much altered as to speed. This has been accounted for in two ways: first, the modern sportsman sits, for the most part, down on his saddle, whereas the sportsman of olden times stood up in his stirrups, and, when his horse fell with him in his gallop, was nearly certain to fall on his head. Secondly, he did not ride the well-bred, superiorly-actioned horse that the modern sportsman rides, which would account for his falling oftener in his gallop, and particularly as the surface of the country, in his day, was very uneven and uncultivated compared to what it now is. Neither was the hunting cap of much service to him in accidents of this description. On the contrary, from its being so low in the crown, as it was then made, coming in immediate contact with the top of the head, the concussion was greater if he were thrown upon his head, than if it had been cased in a hat which, from the depth of it, would break the fall.

In all falls, the horseman should roll away from his horse as soon as he possibly can, lest in his struggle to rise again he strike him with his legs or head. It frequently happens that the horse himself rolls after he falls, and, if in the direction in which his rider lies, is apt to crush and injure him. Indeed, there is scarcely any hard rider who has not been thus served; but here again self-possession often stands his friend. When he sees the body of his horse approaching him, he frequently saves himself by meeting it with one of his feet, and, by obtaining a fulcrum, shoves his own body along the ground out of his reach. Coolness in this hour of peril, likewise serves the sportsman in another way. Instead of losing hold of his reins, and abandoning his horse to his own will, as the man who is flurried at this time invariably does, he keeps them in his hand, if not always, perhaps in nine falls out of ten, and thus secures his horse. It was the remark of a gentleman to whom we have before alluded, and who (*singulus in arte*) was, from his desperate system of riding, and despite of his fine horsemanship, known to have more falls than any other man during the time he hunted Leicestershire, that nothing had so low an appearance as that of a man running on foot over a field, calling out, " Stop my horse."

Before quitting this part of our subject, it may be well to observe, that in cases of bad falls, particularly those affecting the head, where the lancet cannot be *immediately* had recourse to, a large wine glassful of equal parts of *strong* vinegar and water, drunk by the sufferer, is found to be very efficacious, from the revulsive powers of the vinegar acting on the general circulation of the system. In countries where there is much timber to be leaped, stiles particularly, calkins to the shoes of the hinder feet of a hunter should never be omitted, as should those feet slip under his body, the fulcrum, to spring from, is lost, and a fall nearly certain.

We have only a few words more to offer to the young sportsman. Nature is invariably the standard of excellence, and unless she have endowed you with a cool head, a vigorous body, and a stout heart, you will not long distinguish yourself in the hunting field, as what is now termed " *a first-flight horseman.*" You may sing with Hector,

> " ——— *The foremost place* I claim,
> The first in danger, as the first in fame;'

but you will not obtain it unless you possess the above named requisites. But having them, do not consider the following admonitions unworthy of your notice: Never ride at impenetrable, or impracticable places; you may get over or through them with a fall, but your horse will surely be the worse for the attempt, and will the sooner sink under you in a good run. Never abandon your horse to himself over any ground, but be sure to hold him fast by his head, either up or down hill, and in soft ground. If you doubt the effect of a tight hand at these times, ask the first Newmarket jockey you meet, and he will fully satisfy your doubts. In the daring movements of that " *lawless moment,*" which the first start after hounds, in some countries, may now be termed, from the desperate attempts hard-riding men make to get the lead, do not fail to have your eyes about you, and also keep a good command over your horse. In plain English, *do not ride over any man.* Some of the worst accidents to sportsmen have arisen from this cause. In the first place, one man will often ride so close to another who is going to leap a fence, that if the first horse falls, the second is almost certain to leap either on or over him and his rider, as he can rarely be pulled up, or even turned, in so short a space. But even should the second man see the first man's horse in the act of leaping the fence, he should allow him some time to get away from it, for in the event of his clearing it, it is still possible he may fall, by stumbling over something after landing; stepping into a grip or rut, or into false ground, all of which he is subject to, but more especially towards the end of a chase, when, of course, his strength and action are reduced. It is better, if you can, to take a line of your own than to follow any one at this time, as your horse is now fresh; and, by not having cause to pull him up to let others go before you, you have a better chance to get a good start, which gives you a great advantage. When once along side the pack, quit them not until they have finished their work, or at least as long as your horse can go without trespassing too hard on his powers. If, however, you get the lead and can keep it for forty minutes, *best pace over the grass*, with rasping fences and two wide brooks in your way, the laurels Cæsar won would be weeds, and withered ones too, compared with those which would, for that one day, be yours.

There have been, and are now, some splendid specimens of horsemanship, and the management of horses in other ways, amongst servants, and it appears there always were such. Amongst the celebrated ones of antiquity we find the following, moving in this humble sphere: Automedon, servant to Achilles; Idæus to Priam; Metiocus to Turnus, king of Rutuli; Myrtilus to Œnomous, a son of Mars; Ceberes to Darius; and Anniceris, servant to Cyraneus. And why should not the servant, by practice, become as fine a horseman as his master? The question appears to be easily answered, namely, that the chances are equal, with equal instruction and experience. But such has not been found to be the case; and although amongst the various huntsmen, whippers-in, and what are known by the appellation of second-horse-men, namely, those grooms who ride horses with hounds, to supply the place of those their masters ride, when they become fatigued, a most humane, as well as economical plan with all who have a stud of hunters, some super-excellent horsemen may be found, the generality of servants are deficient in that first essential to good horsemanship, a fine or sensitive hand. Nor is this a matter of surprise. The nervous influence, proceeding from the organs of touch, may be said chiefly to constitute what is termed the " hand" of the horseman; and that influence may easily be supposed to be greater in a person whose situation in life has not subjected him to rough and laborious employments which must necessarily tend to deaden it. Until of late years the seat of servants was unfavourable to a good hand on their horse, as they, with very few exceptions, rode with too short stirrups, and, consequently, by being not well placed in their seats, were perpetually interfering with their horses' mouths, from their unsteadiness. So fully aware of these objections was the late Mr Childe of Kinlett Hall, Shropshire, that, during the period of his keeping fox-hounds, he had only one servant in his large establishment that he ever suffered to mount the horses he himself rode, and that was William Barrow, afterwards more than twenty years huntsman to the late Mr Corbet in Warwickshire; and who was remarkable for his fine bridle-hand. Notwithstanding this, it may fairly be maintained, that, from the fact of the comparatively small number of good horsemen who have obtained instruction from the schools, there is more of nature than of art in the acquisition of skill and talent on the saddle.

Saddles and bridles form no unimportant feature in the equestrian art, as well as in the establishment of a sportsman. Nothing sets off the appearance of a horse and his rider more than a good saddle and bridle, nor does any thing contribute more to the comfort and safety of the latter than a well-made, roomy saddle, with spring bars for the stirrup-leathers; stirrups rather heavy than otherwise, and sufficiently large for the feet. Some persons, not contented with the spring bars, require spring stirrups as well; but in our opinion, no man can hang in a common stirrup, provided he do not wear thick boots nor use small stirrup-irons. Of the various sorts of bridles, the snaffle is most in use on the turf, and the curb for military horses, hunters, roadsters, and coach-horses. Not one hunter in twenty has a mouth good enough for a snaffle only; although there are a few horses in every hunt that will not face the curb. Some, however, go very well on the snaffle up to a certain period of a run, when all at once they require the assistance of the curb. Such horses should be ridden with a double bridle, so that the rider may have recourse to the curb-bit, when wanting.

There is often great nicety required in fitting a horse with a bridle, if irritable in his temper, or a very hard puller. If the former, he must have a bit of just sufficient severity to control him, and not any thing more. The one called the "Pelham," is well adapted to horses of this description, as it partakes of the double properties of snaffle and curb. With very hard pulling horses, the curb to a severe bit must be used; but the evil of this is, that, after a certain time, the mouth, thus acted upon, becomes "dead," as the term is, and the horse is unpleasant to ride and difficult to turn. To remedy this, three players should be attached to the port of the bit, which, by hanging loosely over the tongue, keep the mouth alive. A bridle of this description, very long in the cheek, is known in the hunting world, as the "Clipper bit," being the one in which that celebrated horseman Mr Lindow rode a horse, called the Clipper, several years over Leicestershire, in which far-famed county he was supposed to be the best hunter going. If a horse rushes at his fences, a moderately tight nose-band is useful, as also to prevent his opening his mouth, and snatching at his rider's hand. The less a horse opens his mouth in his work the better, as it tends to make it dry; whereas, it cannot be too moist for his own good. Bits very high in the port are of course the most severe, owing to the increased purchase; but with every description of bits, care should be taken that they are sufficiently wide for the mouth, so as not to press against the horse's cheeks, and that the headstall is sufficiently long to let the bit drop well into the mouth.

As we read in the 22d chapter of Genesis, 3d verse, that "Abraham rose up early in the morning, and *saddled* his ass," saddles of some sort must have been used in very early days; but few things appear more extraordinary to those persons who look into ancient history, than the fact of saddles *with stirrups* being a comparatively modern invention. Although a French translator [1] of Xenophon, by an oversight, makes a governor of Armenia hold the stirrup of the Persian king when he mounted his horse—"Il lui tenoit *l'etrier* lorsq'il montoit à cheval,"—it is well known that the ancients had no stirrups, but that men of rank among them were accompanied by a person whose office it was to lift them into the saddle, whom the Greeks called ἀναβολευς, and the Romans *strator*. There is no mention of stirrups in any Greek or Latin authors, no figure to be seen in any statue or monument, nor any word expressive of them to be met with in classical antiquity. In the celebrated equestrian statues of Trajan and Antoninus, the legs of the rider hang down without any support; whereas, had stirrups been used at that time, the artist would not have omitted them. Neither are they spoken of by Xenophon in his two books upon horsemanship, in which he gives directions for mounting; nor by Julius Pollux in his *Lexicon*, where all the other articles belonging to horse-furniture are spoken of. The Roman youth, indeed, were taught to vault into their saddles, (*Æneid* xii. 287,)

> ———"Corpora saltu
> Subjiciunt in equos;"

and in their public ways, stones were erected, as in Greece also, for such as were incapable of doing so. As another substitute for stirrups, horses in some countries were taught to bend the knee, after the manner of beasts of burthen of the East;[2] and in others, portable stools were used to assist persons in mounting. This gave birth to the barbarous practice of making captured princes and generals stoop down, that the conqueror might mount his horse from their backs; and in this ignominious manner was the Roman Emperor Valerian treated by the Persian King Sapor, who outraged humanity by his cruelty. The earliest indisputable mention of stirrups is by Eustathius (the commentator of Homer), about six hundred years back, who uses the word *stabia*.

Although the history of the saddle has not exercised the learned world so much as the antiquity of the stirrup, a good deal has been written and said about it. Like all other inventions, it appears to have been suggested by the necessity of making the rider sit easily upon his horse, and some kind of covering, consisting of cloth or leather (skins or hides, perhaps), was placed on the animal's back. These coverings, however, became afterwards extremely costly;[3] they were made to hang down on each side of the horse, and were distinguished among the Greeks and Romans by various names. After they became common, however, it was esteemed more manly to ride without them; and thus we find Varro boasting of having ridden bare-backed when young. Xenophon also reproaches the Persians with having placed as much clothes under their seats, on their horses' backs, as they had on their beds. It is certain that no coverings to the horses' backs were for a long time used in war; and, according to Cæsar, the old German soldiers despised the cavalry of his country for having recourse to such luxuries. In the time of Alexander Severus, the Roman soldiers rode upon very costly coverings, excepting at reviews, when they were dispensed with, to shew the condition of their horses. But we should imagine we must look to later times for the costly trappings of the horse. In his description of the city of Constantinople, the author of the *Letters of the Turkish Spy* says, "The next thing worthy of observation is the Serayan, or house of equipages, where are all sorts of trappings for horses, especially saddles of immense cost and admirable workmanship. There cannot be a more agreeable sight, to such as take pleasure in horses and riding, than to see four thousand men here daily at work in their shops, each striving to excel the rest in the curiosity of his artifice. You shall see one busy in spangling a saddle with great Oriental pearls and unions intermixed, for some Arabian horse, belonging, perhaps, to the Vizier Azem; another fitting a curb or bit of the purest gold to a bridle of the most precious Russian leather. Some adorn their trappings with choice Phrygian work; others with diamonds, rubies, and the most costly jewels of the east."

---

[1] D'Ablancourt.

[2] See Silicus Ital., lib. 10. 465,—

> "Inde inclinatus collum, submissus et armos
> De more, inflexis præbebat scandere terga
> Cruribus."

[3] See Virgil, *Æneid* vii. 276, viii. 552; Ovid, *Metam.* lib. viii. 33; also Livy, lib. xxxi. cap. 7, who speaks of a man who dressed his horse more elegantly than his wife.

But to return to the history of the saddle, its invention, and general use, the latter a point very difficult to be ascertained. The word *ephippium*, by which the ancient Romans expressed it, being merely derived from the Greek words ἐπὶ, *upon*, and ἵππος, *a horse*, leads us to conclude that, by degrees, the covering spoken of was converted into a saddle. The Greek word ἕδρα, used by ancient authors, is believed to have been to express a saddle, and is more than once used by Xenophon, in his *De Re Equestri;* and Vegetius, who wrote on the veterinary art nearly 400 years B. C., speaks of the saddle-tree. Perhaps the clearest proof of the use of any thing approaching to the form of the modern saddle, is the order of Theodosius (see his Code), in the year 385, by which such persons as rode post-horses in their journeys were forbidden to use those which weighed more than sixty pounds; if heavier, they were ordered to be cut to pieces. What would the people of those times have thought if they could have seen one of our Newmarket racing saddles, weighing under four pounds, but giving the rider a very comfortable seat. The order here alluded to, doubtless applied to something resembling a saddle, although of rude workmanship, as its weight bespeaks. Every traveller, we may conclude, was provided with his own saddle; and about this time the Latin word *sella* more frequently occurs. In the fifth century, again, we find articles bearing something of this stamp, and made so extravagantly magnificent as to call forth a prohibition by the Emperor Leo I. against any one ornamenting them with pearls or precious stones. The saddle-tree is also mentioned by Sidonius Apollinaris, a Christian writer, who was born A. D. 430; and in the sixth century, the saddles of the cavalry, according to Mauritius, who wrote on the military art, had large coverings of fur; and about this period, the Greek word σελλα (*sella*) is used. It is considered probable, however, that the merit of the invention of saddles may be due to Persia, not merely from the circumstance of Xenophon's mentioning the people of that country as being the first to render the seat on the horse more convenient and easy, by placing more covering on their backs than was common in other parts, but also because the horses of Persia were made choice of for saddle-horses in preference to any others. That the word saddle is derived from the Latin word *sedeo*, to sit, may fairly be presumed. That the proper saddle itself, however, was unknown in England until the reign of Henry VII., we have good reason to believe; and in Ireland, from the absence of any representation of it on their coins, it may be conjectured, not till many years subsequent to that period. The woman's saddle, called by us the side-saddle, first appeared in Richard the Second's time, when his queen rode upon one; but from the pictures of men and women's saddles used in England's early days, we find they were miserable apologies for our modern saddles. Indeed, at the present time, Great Britain is the only country in which proper saddles are made. Hunting saddles should have their pannels well beaten and brushed to prevent sore backs; and no sportsman, even if light, should use a short saddle, under sixteen inches from pummel to cantle.

The antiquity of the spur does not appear to have much excited curiosity; but the use of this instrument was known in the very earliest age of which we have any satisfactory history. At least we may presume that it was so, from the Hebrew word signifying horseman (*Pavash*), appearing to be derived from a Hebrew root signifying to *prick* or *spur.* So at least says Buxtorff; and he adds, that the horseman, or spurrer, was so called on this account: *Eques quod equum calcaribus pungat;* and he quotes Eben Ezra in confirmation of his opinion: *A calcaribus quæ sunt in pedibus ejus.* Spurs occur but seldom on seals, or other antiques, in the eleventh century, but in the thirteenth they are more frequent. As it is necessary that a horse should obey the leg as well as the hand, all military and parade horses are ridden in spurs; and, as we have already said, they are very useful to the sportsman in riding across a country, particularly in the act of opening gates; also all race horses that will bear them are ridden with them, because, should punishment be wanting in a race, it is more easily inflicted by the heel than by the hand; add to which, these horses not only require the jockey's two hands at the same time, but are apt to swerve, or shut up, if struck severely by the whip.

Race-Riding, or Jockeyship.—Race-riding and riding over a country cannot be called sister arts. Indeed the former bears little relation to any other system of horsemanship, because, from the rapidity with which the race-horse gets over the ground, there is neither time nor necessity for a display of the various aids which it is in the horseman's power to afford to his horse in most other cases. Nevertheless, the very refinement of the art, the nice and delicate hand, together with a firm and strong seat, is absolutely essential to a good jockey. Neither is this all. He must possess a stout heart and a clear head.

Something like jockeyship was practised in very early times, the Greeks having introduced it at their celebrated games. In the 33d Olympiad they had their race of full-aged horses. In the 71st Olympiad they instituted that for mares called the Calpe, bearing a resemblance to our Oaks Stakes at Epsom; and an interesting anecdote is handed down to us, relating to this race. A mare, called Aura, the property of one Phidolas, a Corinthian, threw her jockey, but continued her course as if he had kept his seat, increasing her pace at the sound of the trumpet, and, finally, as the story goes, presenting herself before the judges, as if conscious of having won. The Eleans, however, declared her to be the winner, and allowed Phidolas to dedicate a statue to her. In the 131st Olympiad, the race of the πῶλος κέλης, or under-aged horses, was established; but with respect to all these races, we are left in obscurity as to the weight the horses carried, as also the distance they ran; and whether or not such matters were regulated by their age, and not at all by their size. It is the general opinion that they were left to the discretion of the judges (the Hellanodics, as they were called), who regulated all matters at Olympia, as the members of our Jockey Club do at Newmarket; but, as may be expected from the character of the times, exercising a power over their brother sportsmen, which would not be relished at the present day, although, in some respects, well worthy of imitation. For example, they not only excluded from the games and imposed fines upon such as were convicted of fraudulent or corrupt practices, but inflicted bodily correction upon them besides. But some very interesting facts are the result of the rigid scrutiny of this Elean Jockey Club. Alexander the Great was ambitious of obtaining the Olympic crown, but was objected to as being a Macedonian, the prize he wished to contend for being confined to Grecians. Alexander cleared himself by shewing, that although he was a prince of Macedon, he was descended from a family that came originally from Argos; and the Hellanodics allowed him to start, but he did not win. Themistocles objected to Hiero, King of Syracuse, as a tyrant, and proposed that the magnificent pavilion which contained his race-horses should be pulled down. The objection, however, was overruled, and he became a winner; but we do not wonder, that, in a Grecian assembly, the name of tyrant should have been abhorred.

The seat of the jockey is one of peculiar elegance, heightened by the almost universal symmetry of his form, or figure, for very few ill proportioned men are seen in the racing saddle. The good appearance of the jockey is also increased by the neat fit of his clothes; his appropriate costume to his calling; the extreme cleanliness of his person, produced by his necessary attention to it during his preparatory course of exercise; and, though last, not least, his almost affinity with the noble animal we see him mounted upon. But for this he is indebted to Nature—to the relation that the bodies of animals hold to natures altogether external to their own; and it is most happily exemplified in that of a man to his horse, which appear to have been especially formed for each other. But, as a celebrated moral philosopher has observed, "There is throughout the universe a wonderful *proportioning* of one thing to another. The size of animals, of the human animal especially, when considered with respect to other animals, or to the plants which grow around him, is such, as a regard to his conveniency would have pointed out. A giant or a pigmy could not have milked goats, reaped corn, or mowed grass; *could not have rode a horse*, trained a vine, or shorn a sheep, with the same bodily ease as we do, if at all."

Previously to describing the proper seat of the jockey, we will now endeavour to exhibit him in the most likely form to acquire that seat. In height he should be about five feet five or six inches. We are aware there are several excellent jockeys under this standard; but they do not look so well on their horses, neither can they be so firm in their seat from want of a better clip, which the firm grasp of a longer thigh gives them. He should be rather long in the fork for his height, with low shoulders, rather long arms, moderate length of neck, small head, and a very quick eye. He should be of a naturally spare habit, to save the expense to his constitution by wasting; but he should have as much muscle in his arms and thighs, as his diminutive form will admit of; in short, to ride some horses at such very light weights, he should be a little Hercules. But there must be nothing like rigidity in his frame. On the contrary, there should be a great degree of pliability about his arms, shoulders, and back-bone, to enable him to be in perfect unison with his horse. He should have very free use of his hands, so as to change his reins from one to the other in a race, and to whip with the left, as well as with the right, when occasion requires it; he should possess much command of temper; and, lastly, he should have the abstinence of a Brahmin.

The seat of the jockey may be described in a few words. He should sit well down in his saddle when he walks his horse to the post, with his stirrups of moderate length, so as to enable him to clear his pummel, and have a good resisting power over his horse. No man can make the most of a race-horse with long stirrup leathers, because, when he is going at the top of his speed, he sinks down in his fore-quarters, in his stride, to the extent of several inches. It was calculated that Eclipse, naturally a low fore-quartered horse, sank nearly eight inches. The circumstance, then, of the use of the stirrup, in ancient racing, being unknown, fully accounts for racing on horseback as we now race, being, comparatively with chariot-racing, but little resorted to; and the excellency of a jockey in the Olympic Hippodrome, consisting more in a sort of harlequin feat of jumping from one horse, and vaulting upon another, in a race, than riding and finishing it, as it is now finished, in a severe trial of speed, bottom, and jockeyship. Indeed, some racers go with their heads so low as to bear up their rider from the saddle whether he will or not, and they would pull him over their heads, if he had not the power of resistance from his stirrups. Much nonsense was written by the late Samuel Chiffney, in a pamphlet called *Genius Genuine*, on riding the race-horse *with a slack rein*, which system, although we by no means approve of a hard, dead hand upon any horse, we are convinced can never be put into practice with advantage to either the horse or his rider. Exclusive of the necessity of restraining a free horse, who would run himself to a stand-still if suffered to do so, or, in making what is called a waiting race, all race-horses feel themselves relieved by a strong pull at their heads, and many will nearly stop, or, at all events, very much slacken their pace, on finding their heads loose. In our opinion, the hand of a jockey on his horse should always be firm, though at times delicate to an extreme; and he should never surprise or disturb the mouth of his horse, in his race, by any sudden transition from a slack to a tight, or from a tight to a slack rein. In fact, every thing in horsemanship is best done by degrees, but at the same time with a firmness and resolution which a horse well understands; and the hand which, by giving and taking, as the term is, gains its point with the least force, is the best and most serviceable, as well as most agreeable to a horse.

Considering the variety of horses of all forms, shapes, and tempers, that a jockey in much repute rides in the course of a year, the necessity for a good bridle-hand is obvious. Some thorough-bred ones have their necks set so low on their shoulders, that they bend first down, then upwards, like a stag's; and were it not for the power of their rider, such horses would absolutely look him in the face. Others have the upper line of their necks, from the ears to the withers, too short. A head attached to such a neck as this is very difficult to bring into a good place, because the inflexibility of it will not admit of its forming an arch; for in long and short-necked horses the number of the vertebræ, or neck-bones, are the same. On the other hand, some horses' necks are as loose as if they had joints in them, and consequently have the power of tossing up their nose almost in defiance of their rider's hand. Others get their heads down in their gallop, in the act of reaching to get more liberty of rein, snatching at their rider's hand with great force. Some pull very hard, and others will not pull enough. Were it not, then, for the tackle in which these low-necked, short-necked, stiff-necked, loose-necked, snatching, pulling horses are ridden in, even the fine hand and firm seat of a first-rate jockey would not be a match for them; and, as it is, it is as much as he can do to manage them; but they would be nearly their own masters with a man on their back who had neither one nor the other. This tackle consists, in addition to the bridle, of the common martingal, with a spare martingal rein, independent of that to the snaffle-bit; a gag-bit and rein, and the martingal running rein. The first, the common martingal-rein, is merely to prevent a loose-necked horse throwing his head up. The jockey uses it altogether, or lets it lie on his horse's neck till he wants it. The gag-rein, from its severity, is generally knotted, and remains untouched till wanted. Its use is to prevent a horse getting his head down, when he goes too much on his shoulders, or bores, and is consequently very difficult to ride, and be made the most of in a race. By *gradually* giving and taking with this and the snaffle-rein, the jockey gets his horse's head into a proper place, and rides comparatively at his ease. We say "gradually," because if done with violence it may cause him to alter his stride. The running martingal-rein (the most common now in use, particularly with young things), is merely to steady a horse's head, and to give his jockey more power over him to prevent his breaking away with him in a race, and to enable him to pull him up at the end of it. No hard puller, or very free-going racer, is ridden without this running martingal-rein. The jockey uses it much in the same way as he uses the snaffle-rein, giving and taking with it in his pulls, so as to keep his horse's mouth alive, and thereby bring his head into a proper place. The necessity for this perfect command of the race-horse, by some one of these means, is obvious, when we see how often they are huddled together in a race, and knowing that, if a foot of either of them should strike or get locked in that of another, a fall is the inevitable consequence. Besides, no horse can exert his utmost speed for any length of time, unless he will allow himself to be handled by his rider, and pulled well together, to prevent his over-striding as well as over-pacing himself. These check-reins can all be used with the double curb-bridle, if necessary, though they seldom are, with the exception of the first, the common martingal-rein. It is pleasant to see a race-horse go with his head in a good place in a simple snaffle-bridle, without any additional reins; and no doubt it must be as agreeable to the horse, but it is rather a rare sight, and particularly with young things. That the snaffle-bit is the best in which the race-horse can be ridden, there cannot be a doubt, not merely on account of his being able to support himself to a certain degree in his gallop, by leaning upon it to the extent his rider permits him, but because his jockey can pull his head any way he likes, to the right or to the left; as in a turn, for instance, or to avoid treading on another horse's heels, which is before him; whereas the curb-bit only acts in a straight line. It is better, however, to have recourse to the curb, than to let a hard-pulling race-horse get the better of his jockey, and overpace himself at any period of his race.

We will now bring our jockey to the starting post, where the first thing he does is to strip. Having inspected the saddling of his horse, and found every thing about him secure, he cocks up his left-leg, and is chucked into his saddle by the trainer, who generally wishes him "*luck*" as he performs this office for him. After he has seated himself firmly down in it, and tried the length of his stirrup-leathers, he takes his "up gallop," as he calls it, of perhaps half-a-mile, his trainer generally leading the way on his hack; and then walks his horse quietly to the starting post. But his method of starting his horse depends entirely on circumstances. If, for a half-mile race, in which a good start is a great advantage, he catches fast hold of his horse's head, and, if he will not start quickly without, sticks both spurs into his sides as soon as the word "go" is given, taking his chance of getting his head down into its place when and how he can. If, for a two-mile race, or over that distance, he need not be in such a hurry at starting, provided he do not lose too much ground; but all this must in great measure be regulated by his orders, whether to make running or to lie by, and wait. We will, however, put him in all these different situations.

The Half-mile Race, generally straight. Orders, "*To make running.*" Having turned his horse round *beyond*, or we should rather say *behind*, the post, he brings him as quietly as he can back to it, with his near-side bridle-rein passing outside of, and over the lower part of, the palm of the left hand, and then pressed firmly by the thumb, and with the off-side rein between the middle and third fingers of the right hand, in which he also has his whip; but, at starting, and throughout a race, unless obliged to strike his horse, a jockey always holds his horse's head with both hands. If a double rein to a curb-bit is used, the near-side rein passes between middle and third fingers of the left hand, and the off-side one between the middle and third fingers of the right hand. On the word being given, as we have already said, he sticks the spurs into his horse's sides, or, by any other means in his power, gets him on his legs, that is, on his speed, as soon as he possibly can, dropping his hand to him to enable him to feel his mouth. He lets him go perhaps half the distance he has to run with only his head hard held, before he gives him his *first* pull; but this event (the half-mile race) being soon over, there is no time for much speculation, and the pull must be but a short one. He then runs up to his horses again; lives with them to the end and wins, if he can, without a second pull; but if he finds other horses too near to be pleasant, or, in other words, appearing to be as good as his own, he takes a second pull within the last one or two hundred yards, when he again lets loose and wins. The same directions hold good in a mile race, with the exception that the jockey need not be quite so much on the *qui vive* at starting, and his pulls may be longer, and the last further from home.

The Half-mile Race. Orders, "*To wait.*" In this case the jockey gets well away with his horses, but never more than a length or two behind any of them, as more than that distance is difficult to make up in so short a race. Within a hundred and fifty, or, perhaps, two hundred yards of home, he gets "head and girth," as the term is, with the leading horse, and then lets loose and wins.

The Mile Race. Orders, "*To wait.*" The jockey may start last of all if he like, but he must not lose much ground. However good judge a jockey may be of *pace*, it is a fault to lie far out of his ground. Let him then also lie well with his horses all the way, creeping up to them by degrees, and not quit them to win till he feels certain he has the race in his hand; that is, till he sees that the other horses have overmarked themselves by the pace. His orders to wait have been given him from the supposition or knowledge that speed, not stoutness, was the best of his horse, and, consequently, that if he had made the running or "play," he would not have run home.

The Two-mile Race. Orders, "*To make running.*" Nothing, next to the struggle of the few last yards between two horses very nearly equal, called on the Turf "the set-to," is so difficult in racing horsemanship, as making running or "play" by a jockey, solely for the benefit of the horse he himself is riding. In other words, it is a great accomplishment in a jockey to be a superior judge of *pace*, that is, of not merely the pace he himself is going, but how that pace affects the other horses in the race. And this task is more difficult with some horses than with others, and especially with idle or lurching horses, which, when leading, require urging by the hand or leg every yard they go. In this case, the jockey works hard to keep his horse going. He has to use his hands, arms, legs, and feet, and occasionally to turn his head round, with all his limbs in action at one and the same moment, and yet not disturb his horse's action; and this, in addition to great anxiety of mind, lest he should upset his horse, and so lose the race. The upshot is, if his horse answers the opinion entertained of him, by cutting up his competitors by severe "play," he wins his race, and has the character of being a stout, honest horse.

The Two-mile Race. Orders, "*To wait.*" In this case the jockey goes off at a steady pace, with a good hold of his horse's head, as near to the other horses as he likes, but not attempting to go in front. Thus he continues in his place to within a certain distance from home, probably specified in his orders, when he brings out his horse, as the phrase is, challenges all the others at once, and wins, if his horse be good enough. This is one of the easiest tasks a jockey has to perform, and if he is pleasantly mounted, he gets an agreeable ride. We shall say little of races more than two miles, for two reasons: First, because the same observations apply to them as do to those of two miles, with proper allowance for the extra distance; and, secondly, because four mile races are now very nearly abolished. In the latter, the chief qualification for a jockey is strength of constitution and a firm seat, added to a very correct idea of pace, for a four-mile race seldom comes to a very nice point at the finish.

The duty of a jockey is to win his race if he can, and not to do more than win it. A neck is sufficient if he have the race-hand; but he should win by a clear length whenever he is in doubt as to the state of the horses he is running against. This is a nice point for a jockey to decide upon, and one which is highly esteemed by his employers, who are always anxious that the powers of their horses should not be unnecessarily exposed. Perhaps one of the finest specimens of science in this peculiar department of the art of horsemanship, was displayed by those celebrated Newmarket jockeys, Robinson and Chiffney, in a struggle for the St Leger stakes at Doncaster in 1827.

All good jockeys avoid the use of the whip as much as possible. When a race-horse is in the fullest exercise of his powers and doing his best, it is unnecessary, for it cannot make him do more; but the blow of a whip often does harm, particularly if it fall under the flank. Instead of its having the effect of making the horse extend himself over a larger surface of ground, it may have quite a contrary effect, from his shutting himself up, as it were, or shrinking, to avoid the blows. The spur, properly used, is a much better instrument for increasing the speed of a horse, although there are times when the application of the whip, or the mere act of flourishing it in the hand, is eminently serviceable to the jockey. We mean when his horse hangs to one side of the course or the other, or towards other horses in the race, or exhibits symptoms of running out of the course, or bolting. A jockey ought to be able to use his whip with vigour when necessary, and (though this do not often happen) with his left hand, as well as with his right, in case of his losing what is called the whip-hand, when he cannot use his right.

The nature and form of race-courses are points very much to be considered in jockeyship. Such as are quite flat and straight are, of course, the least difficult to ride over; but a little variety of ground is favourable to the horse, and not unpleasant to the jockey. Those which are hilly require much judgment to know where to make the best play; or, in other words, what part of the ground is best suited to the action and nature of the horse. All horses, however, require holding hard by the head both up and down hills, or they will soon run themselves to a standstill. A small ascent is desirable to finish a race upon, as it is safer for the riders, who occasionally lose their horses' heads in the last few strides; and also in pulling them up, when they are often in an exhausted state, and, consequently, liable to fall or slip, on uneven ground, especially if it be in a slippery state from drought or wet. Most country courses have turns in them, which must be provided against in two ways. First, the jockey, at starting, should endeavour to get the whip-hand of his competitors; that is, he should try to be on the right side of the other horses, if the posts are on his right hand, and on the left side of them, if they are on the left. He will, of course, in this case have to describe a smaller circle of ground in his race than the other horses will have, and also, if the turns be on his right, the use of his right or whip-hand, at any period of the race; which he would not have, if he were on the outside of one or more horses in the race. But he must be wide awake over a course with turns in it, as some of them are very difficult to make, especially if all the horses are in strong running at the time, and the one he is riding should not be what is called kind at his turns, or an easy horse to ride. He must not omit the precaution of lying a little out of his ground before he comes to a turn, so as to make it pretty close to the post, when he will be less likely to disturb the action of his horse, than if he made it at a more acute angle, which he would necessarily do, if he did not take this sweep. Another precaution is also necessary; as, when a horse is galloping in a circle, the first leg towards the centre takes the lead, the jockey should endeavour to make his horse lead with the leg next the turn, which will prevent his changing his leading leg in the turn, which he will be obliged to do, unless a very easy one indeed. This is best effected by keeping his head a little to the opposite side of his body; that is, a little to the left hand, if the posts are to the right, as they generally are, and *vice versa*. When a race-horse is extended at the very top of his speed, his head should, of course, be kept straight; but as he is never going his best pace in his turns, the keeping of his head away from them, for the purpose we have noticed, cannot be at all injurious to him. In quite straight running, it is, we believe, of very little consequence with which leg the race-horse leads.

Our remarks on the art of race-riding may be concluded by stating the manner in which horses of various tempers, dispositions, and capabilities, are to be ridden, with the best chance of being made the most of. Nine racers in ten are free-going ones, if not hard pullers. On one of this description, the great art of the jockey is to economize his powers according to the length he has to go, as also the weight he is carrying, so as not to let him over-mark himself, and have little or nothing left in him at the finish. If other horses make running, this can only be done by his sitting perfectly still in his seat, dropping his hands, and having fast hold of his horse's head. The less he interferes with his mouth the better; and if he likes to be well up with the other horses, he is better there, supposing him not to be a regular jade, than pulled at, to be kept back. Temper is a great thing in this case, we mean in the jockey; for a hasty horse and a hasty rider are sure to disgrace themselves. Every unnecessary movement in the one is instantly responded to by the other, who becomes flurried, and pulls more determinedly than he did before.

The lazy, sluggish, or "craving" horse, as trainers call him, requires riding from end to end of his race. By this we mean, that although the body of his jockey should not move, he is often obliged to raise his hands off his horse's withers, to shake him now and then; as well as to use his feet to urge him to a better pace, or even to keep him at the one he is going. Indeed, he will sometimes require a blow with the whip, or at least to be very much roused, to make him extend his stride towards the finish of his race. This is the sort of horse that used to distinguish himself over the Beacon Course at Newmarket, when four-mile races were more in fashion than they now are, and was, of course, not thought the worse of by his owner, whatever he may have been by his jockey, for taking so much riding to make him do his best.

But the most ticklish and difficult horse, next to the determined restive one, or bolter, is what is known by the appellation of the "Flighty Horse," one which is as difficult to train as he is to ride, being delicate in constitution, of extremely irritable temper, and very easily alarmed, either in his stable or out of it. Nothing, in short, can be done with him, but by the very gentlest means; for if once ruffled, he is very hard to be appeased. The jockey, then, that has to ride a horse of this description, should have a temper the very reverse of his, and a hand as delicate as a woman's. He must also indulge him in every way in his race save one, which is, in not allowing him to overpace himself. But here, also, he must be careful; for this horse will neither bear to be pulled nor hustled, but must be let to go nearly in his own way, with the exception of being kept well together by a steady hold of his head. If challenged in the race, he must accept the challenge, and come out of the conflict as well as he can. He is too often a jade; at all events, he should always be ridden as if he were one; and the same precautions, as to steadiness of seat and hand, that we have recommended for the free-going horse, or hard puller, should be observed with regard to him.

Jockeys delight in riding a fine-tempered racer; such as Zinganee was in the year 1830, and of which year he was considered the best horse. In a plain snaffle bridle, without even a martingal, as he was ridden, and with an obedient mouth, it is a pleasing instead of an irksome task. A horse of this description is easily held, is kind at his turns, in fact, will nearly make them of his own accord; will either wait or make play, as his rider's orders may be; and when called upon to challenge, is ready to do his best. More than this, he is always going within himself, because he is obedient to his jockey's hand; and his temper is at least equal to 4 lb. weight in his favour.

We now conclude our remarks on jockeyship with a short description of the finish of a race, confining the scene of action to the last four hundred yards; the leading horses being, we will suppose, some head and girth, others head and neck, and others head and head. We will further suppose our jockey to be in the midst of them, with very little left in his horse, but just enough to win his race. The set-to is about to begin, or, in other words equally technical, he is about to "call upon his horse." But before he does this, he alters his position in his saddle. He has been previously standing up in his stirrups, with his body leaning forward over the horse's withers, and his hands down, somewhat below them. He now changes the position of both body and hands: he seats himself firmly down in his saddle, his body catching, as it were, the stride of the horse; and, raising his hands off his withers, first gives him an easy pull, and then, and not till then, the set-to begins. He now moves his hands, as if describing a circle, by way of rousing his horse, by "shaking him," as it is called; and although he does not quite slacken his reins, he allows him to reach with his head, as a distressed horse will always do, and which is technically termed "throwing him in." Then now comes the last resource. If he finds, when within a few yards of home, that he cannot win by these means, and that his horse appears to sink in the rally, he stabs him a few times with his spurs; gets his whip up in his right hand, giving a good pull with his left, and uses it as occasion may require.

Steeple-Chase Racing.—A new system of racing jockeyship has come into fashion in Great Britain and Ireland within the last twenty years, which, however in character with the daring spirit of our present race of sportsmen, we know not how to commend. We think it an unreasonable demand on the noble energies of the horse, to require him to go so very nearly at a racing pace (for such we find to be the case) over rough and soft ground, instead of upon smooth and elastic turf, with the addition of having too often a country selected for him to run across, abounding in almost insurmountable obstacles, as well as, in some cases, deep rivers, as likewise under a heavy weight. One human life has already been the victim of this practice, and, we are sorry to say, several horses have died from over-exerting themselves in steeple-chases. We have reason to believe, however, that they will not become a lasting amusement of British sportsmen.

Qualifications for a Steeple-Chase Rider.—These are exactly what are wanting in a very fast run over a stiffly enclosed country with fox-hounds; namely, a fine bridle-hand, a steady seat, a cool head, undaunted courage, and, above all things, great quickness, and very prompt decision. But the steeple-chase jockey has one evil to guard against, which the racing jockey is, comparatively, but little subject to, and this is a fall. The best preventive of it is keeping a horse well together, and making him go in a collected form at his fences, as well as over rough ground, which, when going nearly at the top of his pace, will be only done by a rider with a very good bridle-hand. But, at the same time, he must be careful not to overmark his horse, or he will not be able to rise at his fences when he gets to them. And here lies the great difficulty after all, as far as the horse is concerned. He must go, at least he is called upon to go, at a much quicker rate than he can reasonably be expected to maintain, for any considerable length of time, without becoming distressed, because his competitors in the race are also doing so, and he will be left behind, to a certainty, if his rider do not endeavour to make him keep with them. That horse, then, has the best chance to win who, barring a fall, is the stoutest runner and surest fencer, and whose rider is good enough, and strong enough, to give him all the assistance he requires, at least as much as a rider can give him, to enable him to struggle through his difficulties to the end. But there is one quality in a horse, especially calculated for steeple-chace racing, and that is *quickness.* Our readers can distinguish between a quick horse and a fast horse; the fast horse may require to be going some time before he begins to extend himself nearly to the extent of his speed; whereas the quick horse is on his legs in a few hundred yards. A similar difference is observed by sportsmen in the fencing of horses. Some are on their legs again, and almost instantly away, as soon as they alight on the ground, be the fence ever so large, whilst others dwell for some time after landing, previously to their recovering their equilibrium, and so lose time. It is evident, then, that a quick horse, with a quick man on his back, is best adapted to a steeple-chase; and would beat another, supposing leaping and other qualifications, this excepted, to be equal, who could give him half a stone weight over the Beacon Course, and beat him. Steeple-chase racing never can be a game to bet money upon, from the almost perpetual liability to accidents; nor do we think it fair that such animal suffering as we find it creating, can be considered a proper medium for that purpose, allowing for a moment that such a medium must be found. But has man, who may be considered the delegate of Heaven over inferior creatures, the right thus to speculate upon their endurance of suffering? We think not; but of this fact we are certain, There is hardly a more certain token of a cruel disposition than the *unnecessary* abuse of animals which contribute, as the horse specially does, to our advantage, convenience, and pleasures; and even a Pagan has told us that he who smothers a cock, *without necessity*, is no less guilty than the man who smothers his father.

Neither is it a great compliment to this species of horsemanship to show its origin, which is thus given in a work called *The Gentleman's Recreation*, written nearly two hundred years back: "But before I enter upon the subject proposed," (training of horses) says the author, "I think it convenient to tell you the way our ancestors had of making their matches, and our modern way of deciding wagers; first, then, the old way of trial was, by running so many train scents after hounds, this being found not so uncertain and more durable than hare-hunting, and the advantage consisted in having the trains laid on earth most suitable to the nature of the horses. Now others choose to hunt the hare till such an hour prefixed, and then to run the *wild-goose chase*, which, because it is not known to all huntsmen, I shall explain the use and manner of it. The wild-goose chase received its name from the manner of the flight which is made by wild-geese, which is generally one after another, so that two horses, after the running of twelve score yards, had liberty, which horse (qr. rider?) soever could get the leading, to ride what ground he pleased, the hindmost horse being bound to follow him within a certain distance, agreed on by articles, or else to be whipt up by the tryers or judges which rode by, and whichever horse could distance the other, won the match. But this chase was found by experience so inhumane, and so destructive to horses, especially when two *good* horses were matched, for neither being able to distance the other, till ready both to sink under their riders through weakness; oftentimes the match was fair to be drawn, and left undecided, *though both horses were quite spoiled*. This brought them to run train scents, which was afterwards changed to three heats, and a straight course." Our readers will acknowledge the resemblance between the modern steeple and the ancient wild-goose chase; and we trust that ere long, the example of our ancestors will be followed, and the man who is capable of exhibiting his horsemanship as the winner of a modern steeple-chase, will reserve his prowess for a better if not a nobler cause.

(B. B. B. B.)

HORSENS, a town of Denmark, at the mouth of a fiorde in Jutland, in the province of Ribe. It contains two churches, 504 houses, and 3650 inhabitants, who carry on fisheries, and some trade in corn and butter. Long. 9. 43. E. Lat. 55. 52.

HORSHAM, a market and borough town in the hundred of East Easewrith, and rape of Bramber, in the county of Sussex, thirty-six miles from London. It is an ancient place, according to tradition, built by Horsa, the brother of the Saxon Hengist. It stands on the upper part of the river Arun, in a fertile district. The county jail, a new building, is in the town, and also a county-hall, in which the assizes are held alternately with the town of Lewis. It is an ancient borough by prescription, and returned two members to parliament till 1832. It now returns one by about 600 voters. The market is held on Saturday, and well supplied. The inhabitants amounted in 1801 to 3204, in 1811 to 3839, in 1821 to 4575, and in 1831 to 5105.

HORSLEY, a town and parish in the hundred of Longtrees, in the county of Gloucester, 101 miles from London. It has a market, which is held on Saturday. The county bridewell is established here. There is some trade in making woollen goods. Formerly a priory existed, whose remains are still visible. The inhabitants amounted in 1801 to 2971, in 1811 to 2925, in 1821 to 3565, and in 1831 to 3690.

HORSLEY, SAMUEL, a very learned prelate of the church of England, the son of the Rev. John Horsley, for many years clerk in orders at St Martin's in the Fields, and afterwards rector of Thorley in Hertfordshire, was born at his father's residence in St Martin's churchyard, in October 1733. He received his early education from his father, and was entered at Trinity-hall, Cambridge, where he applied himself much to the study of mathematics, but, at the same time, perused with care the writings of the ancient and modern divines and logicians. Why he took no degree in arts cannot now be ascertained; we find, however, that, in 1758, he took that of bachelor of laws, and became his father's curate at Newington, which living he succeeded to the following year, and held until his elevation to the Episcopal bench in 1793, as Bishop of Rochester.

In April 1767, he was elected a fellow of the Royal Society, of which he continued for many years an active member, and, about the same time, he published a pamphlet on the Power of God, "deduced from the computable instantaneous productions of it in the solar system." This he allows to be a "very singular and whimsical speculation;" and observes respecting it, that, in all probability, it would "roll down the gutter of time, forgotten and neglected." In 1768, he went to Christ-Church, Oxford, as private tutor to Heneage Earl of Aylesbury, then Lord Guernsey. In 1770, his first mathematical publication, *Apollonii Pergæi Inclinationum libri duo*, was elegantly printed at the Clarendon press. This work, though severely criticised at the time, and, in reality, not distinguished by any peculiar felicity of restoration, does not appear to have injured his rising reputation; for, in November 1773, he was appointed secretary to the Royal Society, and in 1774 he had the degree of doctor of civil law conferred on him at Oxford, and was presented by the Earl of Aylesbury to the rectory of Aldbury in Surrey, along with which he obtained a dispensation to hold that of Newington. The same year he published Remarks on the Observations made in the Voyage towards the North Pole, for determining the acceleration of the Pendulum in latitude 79° 51′. These were addressed to the Hon. Constantine J. Phipps, 4to, and intended to correct some errors committed by Israel Lyons, the mathematician employed on the voyage.

Dr Horsley having long meditated a complete edition of the works of Sir Isaac Newton, issued, in 1776, proposals for printing it by subscription, in five volumes 4to; but the commencement of the undertaking was delayed by severe domestic affliction, nor was it completed until 1785. In the meanwhile, his diligence and proficiency in science attracted the notice of Dr Lowth, who, on his promotion to the see of London in 1777, appointed Dr Horsley his domestic chaplain, collated him to a prebend in St Paul's cathedral, and procured for him the situation, which had been held by his father, of clerk in orders at St Martin's in the Fields. In 1778, during the controversy between Dr Priestley, Dr Price, and others, on the subject of materialism and philosophical necessity, Dr Horsley published a sermon on Providence and Free Agency, in which he attempted to draw a distinction between the philosophical necessity of the moderns and the predestination of their ancestors. This discourse was evidently directed against the writings of Dr Priestley, but the latter did not take any immediate notice of the attack. In 1779, Dr Horsley resigned Aldbury, and, in 1780, was presented to the living of Thorley, which he held, by dispensation, along with that of Newington. In 1783, he became deeply involved in a dispute with some members of the Royal Society, which ended in his withdrawing himself from that learned body.

Dr Horsley was now about to engage in that celebrated controversy with Dr Priestley; which was conducted on both sides in the fiercest spirit of polemical contention, but on that of Horsley with superior learning and ability. In 1782, Dr Priestley published a work in two volumes 8vo, entitled a History of the Corruptions of Christianity; at the head of which he placed both the Catholic doctrine of Christ's divinity, and the Arian doctrine of his pre-existence, in a nature far superior to the human, at the same time representing the Socinian doctrine of his mere humanity as the unanimous faith of the first Christians. Dr Horsley conceiving that the best antidote to the poison contained in this work would be to destroy the credit of the writer, and the authority of his name, made its imperfections, moral as well as literary, the subject of review in a charge delivered to the clergy of the archdeaconry of St Alban's, at a deputation held on the 22d of May 1783. The specimens produced as evidence of the imperfections of the work and the incompetency of the author, may be reduced to six classes. First, instances of reasoning in a circle; second, instances of quotations misapplied through ignorance of the subject; third, instances of testimonies perverted through artful and forced constructions; fourth, instances of passages in the Greek fathers misinterpreted through ignorance of the Greek language; fifth, instances of passages misinterpreted through ignorance of the Platonic philosophy; and, sixth, instances of ignorance of the phraseology of the earliest ecclesiastical writers. Dr Horsley concludes his charge by observing, "I feel no satisfaction in detecting the weakness of this learned writer's argument, but what arises from the consciousness that it is the discharge of some part of the duty which I owe to the Church of God." This vigorous and systematic attack staggered the admirers of Dr Priestley; but he himself felt none of the apprehension with which they were seized. He promised an early and satisfactory answer; predicted that he would rise from his supposed defeat more illustrious than ever; undertook to strengthen the evidence in support of his favourite opinions; flattered himself that he would find a new convert in his antagonist; and even hinted something concerning the shame and remorse with which he felt confident that the latter must be penetrated. Dr Priestley could not but be sensible that his adversary was a man of no ordinary stamp; yet, with a blind self-confidence, he did not profit by this conviction so as to make a careful revision of his writings, but, on the contrary, immediately repeated his former assertions respecting the doctrine of the Trinity, in a publication entitled, Letters to Dr Horsley, in answer to his Animadversions on the *History of the Corruptions of Christianity*, with additional evidence that the primitive Christian Church was Unitarian, 1783, in 8vo. To this production, in which there are more errors of haste and infirmities of argument than could have been expected from one who had so much at stake, Dr Horsley replied in the same epistolary form, by Letters from the Archdeacon of St Alban's in reply to Dr Priestley. The object of these letters, which are seventeen in number, and display great learning and research, is to prove that if the mistakes of Dr Priestley, formerly pointed out, are few in number, they are too considerable in kind to be incident to a well-informed writer; that they betray a want of general comprehension of the subject, and an incapacity to draw right conclusions from the passages cited; that they prove him unskilled in the language of the writers from whom his proofs were professedly derived, and unacquainted with that philosophy, the doctrines of which he pretended to compare with the opinions entertained by the church. Dr Priestley, in his Letters, had attempted to draw his adversary into a controversy respecting the divinity of Jesus Christ; but the latter, knowing that question to have been long since exhausted, defended his own argument, and confined himself to the collection of proofs, from Dr Priestley's publications, of his inability to throw any light upon the subject.

Dr Priestley, finding that his letters had failed to produce the expected impression, and that his antagonist, untouched with either shame or remorse, remained unshaken in his opinion, now lost all temper; and in a second set of Letters to the Archdeacon of St Alban's, which appeared in the autumn of 1784, threw aside all profession of personal regard, or even of ordinary civility. The charge of incompetency and ignorance was warmly retorted, and "the incorrigible dignitary" was charged with manifest misrepresentation of his adversary's argument; with injustice to the character of Origen, whose veracity he had called in question; and with the grossest perversion of ancient history. In a word, he was stigmatised as a "falsifier of history, and a defamer of the character of the dead." Regardless of this reproach, Dr Horsley remained silent for eighteen months. A sermon on the Incarnation, preached upon the feast of the Nativity in 1785, formed the prelude to the renewal of the contest on his part, and was, early in the ensuing spring, followed by Remarks on Dr Priestley's Second Letters to the Archdeacon of St Alban's, with proofs of certain facts asserted by the Archdeacon. This tract consists of two parts; one containing new specimens of Dr Priestley's temerity in assertion; and the other defending the attack upon Origen, and proving the existence of a body of Christians at Ælia after the time of Hadrian, which was the fact upon which the Archdeacon's historical fidelity had been so loudly arraigned by Dr Priestley. With this publication Dr Horsley had intended that the controversy on his part should close; but having been induced to collect and republish what he had written (in one vol. 8vo, 1789), this led to a second perusal of Dr Priestley's Letters, which produced not only many important notes, but some disquisitions of considerable length; and as the Remarks on Dr Priestley's second Letters had elicited a third set, in which he endeavoured to support the veracity of Origen, and to maintain his position respecting the orthodox Hebrews of the church at Ælia, these are replied to partly in the notes, and partly also in two of the disquisitions Towards the conclusion of his Remarks, Dr Horsley observes: "These and many other glaring instances of unfinished criticism, weak argument, and unjustifiable art, to cover the weakness and supply the want of argument, which must strike every one who takes the trouble to look through those second letters, put me quite at ease with respect to the judgment which the public would be apt to form between my antagonist and me, and confirmed me in the resolution of making no reply to him, and of troubling the public no more upon the subject, except so far as might be necessary to establish some facts, which he hath somewhat too peremptorily denied; and to vindicate my character from aspersions which he hath too inconsiderately thrown out."

The reputation which Dr Horsley had now acquired, recommended him to the patronage of Lord Chancellor Thurlow, who presented him to a prebendal stall in the cathedral of Gloucester; and, by the interest of the same eminent person, he was, in 1788, promoted to the see of St David's. As a bishop, his conduct was exemplary and praiseworthy; in this character he fully answered the high expectations of eminent usefulness, which his elevation to the mitre had so generally raised. In his diocese, he carried through a general system of reform, regulated the condition of the clergy, introduced greater strictness with respect to candidates for admission into holy orders, preached frequently in the parish churches, and acted with Christian liberality towards the poor. Bishop Horsley's first charge to the clergy of St David's was delivered in 1790, and deservedly admired, as was also his animated speech in the House of Lords, 31st May 1791, on the subject of the Catholic Bill. These effective displays are understood to have occasioned his subsequent promotion to the bishopric of Rochester and the deanery of Westminster, upon which he resigned the living of Newington.

During the agitating period between 1793 and the close of the century, Bishop Horsley ranged himself on the side of the government, and with great zeal and warmth opposed the enemies of the constitution, and the professors of democratic principles, under which categories were then included all those who sought for reform in the representation of the people as a guarantee for the removal of abuses, and the progressive improvement of our institutions, ecclesiastical as well as civil. As a senator, his talents and activity necessarily gave him weight; and there were few discussions of importance in which he did not take part. He was not, however, an every-day speaker, nor desirous of protracting the debate, unless he had something original or important to communicate. In 1802, he was translated to the bishopric of St Asaph, and resigned the deanery of Westminster. Until 1806, his vigour of body and mind remained unimpaired. In the month of July of that year he went to his diocese, and after a residence of two months intended to visit his patron Lord Thurlow at Brighton, where he arrived on the 20th of September, after learning on the road that his noble friend was no more. On the 30th, he became affected with a complaint in the bowels, which, slight at first, soon terminated in mortification, and on the 4th of October proved fatal. Bishop Horsley died in the seventy-third year of his age.

Dr Horsley was throughout life an indefatigable student; he indulged no indolence in youth, and amidst an accumulation of preferments, contemplated no time when he might rest from his labours. His mind was constantly intent on some pursuit, and, setting a high value upon the fame he had acquired, his ambition was to justify the favourable opinion of the public, and the liberality of his patrons. In classical acquirements, and in the critical knowledge of the languages in which the sacred books were originally written, he stood in the very first rank of excellence. In the mathematical and physical sciences, if he stood not in the first rank, he occupied at least a very respectable station. In metaphysical acuteness and research, he had probably few superiors; whilst, in his proper science of theology, we will venture to affirm that he had none. The ablest champion of orthodoxy that the church had for many years seen, he was so much of an original thinker, and so independent of his predecessors or contemporaries, that his mode of defence was entirely his own, and his style and manner, like Warburton's and Johnson's, though dangerous to imitate, were nevertheless the best, perhaps, that could have been devised in the conflict of opinions with which he was surrounded. In his writings, as in his character, there was nothing lukewarm, nothing compromising. His character and manner were indeed somewhat harsh, and arrogant, and dogmatical; but, whilst due allowance must be made for the heats and errors which controversy engenders, charity induces us to believe that much of his apparent asperity arose from his zeal for the truth, and his high sense of its importance, and that, in fact, he possessed more genuine liberality than some of his most clamorous opponents. He was classed, indeed, and he classed himself amongst High-churchmen; but he was no doubt perfectly sincere in his attachment to the constitution and doctrines of the Church of England; and on more than one occasion he gave proof that he understood the great principles of practical toleration better than some who made louder pretensions to liberality. It is certain, indeed, that he was not only willing, but anxious, to enter into a Parliamentary inquiry into the claims of the Roman Catholics of Ireland, and to grant them whatever that inquiry might shew could be granted with security to the Protestant Establishment, and the Protestant succession.

In his fierce controversy with Dr Priestley, Bishop Horsley had a manifest advantage both in learning and argument; and when we reflect that his adversary aimed at nothing less than the overthrow of the English establishment, and avowed his purpose in language not remarkable either for modesty or for delicacy, we cannot justly wonder that he used strong language in return. Yet it is dignified language; and will not now, perhaps, appear to any candid reader, to be much stronger than the case required. The concluding paragraph of his *Remarks upon Dr Priestley's Second Letters*, affords a striking specimen of his manner as well as of his temper; of a manner, no doubt, sufficiently authoritative and decided, but of a temper which appears to us entitled to the name of Christian. "For eighteen months or more," says he, "it hath been the boast of the Unitarian party, that the Archdeacon of St Alban's hath been challenged to establish facts which he had averred; that he hath been insulted in his character, as a scholar and a man; charged with ignorance, misrepresentation, defamation, and calumny; and that, under all this, he hath continued speechless. He hath at last spoken, in a tone which, perhaps, will little endear him to the Unitarian zealots. It matters not. The time seems yet so distant when the train which they are laying may be expected to explode, that the danger is exceedingly small that he will ever be reduced to the alternative of renouncing his faith, or relinquishing his preferments; or to the harder alternative which Dr Priestley seems to threaten, of a prison with a good conscience, or his present emoluments without one. If those happy times of which Dr Priestley prophecies, should overtake him ere his course is finished; when an Arian or Socinian Parliament shall undertake the blessed business of a second reformation, and depose archbishops from their thrones, and archdeacons from their couches of preferment; he humbly hopes that he may be supplied with fortitude to act the part which may not disgrace his present professions. The probability, however, seems to be, that ere those times arrive (if they arrive at all, which we trust they will not), my antagonist and I shall both be gone to those unseen abodes, where the din of controversy, and the din of war, are equally unheard. There we shall rest together, till the last trumpet summon us to stand before our God and King. That whatever of intemperate wrath, and carnal anger hath mixed itself, on either side, with the zeal with which we have pursued our fierce contention, may then be forgiven to us both, is a prayer which I breathe from the bottom of my soul, and to which my antagonist, if he hath any part in the spirit of a Christian, upon his bended knees will say AMEN."

As a preacher, or rather as a writer of sermons, Bishop Horsley must be allowed to stand in the first class, yet we do not know with whom in that class we can well compare him. In force, depth, and erudition, in precision and distinctness of ideas, in aptitude and vigour of expression, and, above all, in the original powers of thinking displayed in them, Dr Horsley's discourses are unquestionably *sui generis*. But difficult as the subjects often are, which he discusses in them, even ordinary readers, moderately conversant with the Bible, and with the theory and practice of their religion, may derive more advantage from them than from any volumes of sermons which have issued from the press for more than half a century. Even difficulties, and very serious difficulties, Dr Horsley frequently renders plain and practical, by clear, patient, and ingenious criticism; and having fixed his principle on a scriptural ground, and made that ground comparatively clear and easy, he enforces the practical consequences on that direct authority of God which, within the walls of a Christian church, ought to supersede every other. Dr Clarke, in his sermons, which stand in the very first rank of excellence, often treats and largely discusses, Christian subjects, the mysteries of redemption, and the various positive ordinances of the gospel. But he does so with this remarkable difference from Bishop Horsley, that he is never satisfied with any scriptural principle or precept, till he has laboured to render it conformable to what he calls *eternal reason* and *the fitness of things*. Thus, even on subjects of which we should never have known any thing but from Scripture, and which derive all their importance and authority from revelation, we are frequently perplexed with thorny and intricate discussions, intended to accommodate them to this eternal reason and immutable relation of things. The evil of such discussions is, that they are apt to leave an impression on the mind that the obligations of duty rest on something different from, and independent of, the will of God; whereas, to a Christian, the source of the obligation, whether as respects moral or religious duties, is beyond all controversy, the revealed will of God alone. Hence it was that Bishop Horsley, when he had distinctly traced a principle, doctrine, or precept to Scripture, justly conceived that he had done all which a Christian could require to enforce obedience. It may be interesting, it may even be important, to trace the admirable conformity which subsists between the revealed will of God, and the same will as it may be deduced from the nature of things, and the condition of man; but it never can be absolutely necessary to establish this conformity; for whether we are able to trace it or not, the Christian obligation is the same. The supposition that revelation may, in every instance, be accommodated to reason, or, in other words, that a conformity can always be traced between the dictates of reason and the doctrines of Scripture, is a supposition not only fraught with danger, but incompatible with the very import of the term revelation, which necessarily implies the disclosure to man of that which reason could never have informed him of.

Besides the works already mentioned, Bishop Horsley was the author of the following, viz. 1. On the Properties of the Greek and Latin Languages, 1796, in 8vo; 2. On the Achronical Rising of the Pleiades, appended to Dr Vincent's *Voyage of Nearchus*, 1797; 3. A Circular Letter to the Diocese of Rochester, on the Scarcity of Corn, 1796; 4. Another Circular Letter to that Diocese on the Defence of the Kingdom, 1798; 5. Critical Disquisitions on the 18th chapter of Isaiah, 1799, in 4to; 6. Hosea translated from the Hebrew, with Notes explanatory and critical, 1801, in 4to; 7. Elementary Treatises on the fundamental principles of Practical Mathematics, for the use of Students, 1801, in 8vo. Since his death have appeared, 1. Sermons, 1810 and 1812, in three vols. 8vo; 2. Tracts in controversy with Dr Priestley, upon the historical question of the belief of the first ages in the Divinity of Jesus Christ, revised and augmented by the author, with an appendix by his Son, 1812, in 8vo; 3. The Speeches in Parliament of Samuel Horsley, 1813; and, 4. The Charges delivered at his several visitations of the dioceses of St David's, Rochester, and St Asaph, 1813, in 8vo.—(Chalmers's *Biog. Dict.* art. HORSLEY; *Edinburgh Review*, vol. xvii. p. 465, 468.) (A.)

HORST, a town of the Netherlands, in the province of Limburg, and circle of Ruremont. It contains 2246 inhabitants; but is an extensive parish, which has a population of 4490, who are occupied in weaving linen and cotton goods.

HORTENSIUS, QUINTUS, one of the most celebrated orators that Rome produced, the contemporary and rival of Cicero, was born B. C. 114, and eight years before Cicero. He was son of L. Hortensius, who had distinguished himself in his prætorship in Rome, and proconsulship in Italy, by a strict adherence to justice and the ancient laws of his country. His mother Sempronia was grand-daughter to Tuditanus. Of the manner in which he spent his earlier years, we have received no information; but we find him at the age of nineteen (B. C. 95), at once taking a distinguished place amongst the orators of his country. (*Cic. Br.* 64.) The first cause which he undertook was that of Africa, in which he was eminently successful; and shortly afterwards he was employed by the king of Bithynia in his defence before the senate. The breaking out of the Social War, B. C. 90, so alarmed the Romans for the very existence of their power, that all domestic proceedings were for a time suspended, and the youth enrolled themselves for the defence of their country. Hortensius, like others of his own age, joined the army, and in the second campaign was raised to the rank of tribune. It does not appear, however, that he possessed military talents, as we do not find him taking an active part in any warlike proceedings. His ædileship was distinguished by the magnificence of his exhibition of the public games, and by a gratuitous distribution of corn among the people. It was in 70 B. C. that he was first directly opposed to Cicero in the celebrated trial of Verres, but notwithstanding the utmost efforts of his eloquence, Verres was brought in guilty of the charges which Cicero brought against him. The following year (B. C. 69) we find him raised to the consulship, along with Q. Cecilius Metellus; but it was a period during which Rome enjoyed profound peace at Rome, whilst she was triumphing over Mithridates in the east by the arms of Lucullus. The conduct of the war against the Cretans fell by lot to Hortensius, but feeling that the proper arena for the display of his talents was in the peaceful contests of the Forum, he refused to leave Rome, and gave up the commission to his colleague Metellus, who derived the name of Creticus from the subjugation of the island. (*Xiphilin. Epit. Dion.* tom. i. p. 75.) He amassed great riches, and became remarkable for the magnificence of his villas, and his sumptuous mode of living. He opposed with success a sumptuary law proposed by Pompey and Crassus (*Dion.*); and resisted the proposals of Gabinius and Manilius to invest Pompey with powers of so extraordinary a nature, that they seemed calculated to annihilate the independence of Rome. Though the most formidable rival of Cicero in the Forum, he was the intimate and affectionate friend of that orator; and when Clodius threatened Cicero with exile, Hortensius appeared in the assembly of the people in deep mourning, and was attacked by the slaves of that factious tribune. (*Cic. Mil.* 14.) In his latter years, he did not exert himself to maintain the rank to which he had attained, and allowed his glory to be eclipsed by the wonderful powers of eloquence displayed by Cicero. A few days before his death, B. C. 50, he defended the cause of Appius Claudius; and it was in consequence of the exertions which he made in that case that he broke a blood-vessel, which put an end to his life. *Cic. Br.* 94; *Ep. Fam.* viii. 13; *Ep. Att.* vi. 6. Hortensius was first married to Lutatia, the daughter of the celebrated Lutatius Catullus, by whom he had a son, whose conduct gave him great cause of uneasiness, and a daughter, Hortensia, distinguished for her talents, who married Valerius Messala. Hortensius afterwards contracted a second marriage with Marcia, daughter of Philippus, and wife of Cato. This transaction was of a very extraordinary nature, and was little to the honour of any of the parties; but the details may be read in Plutarch (*Life of Cato*). As none of his writings have been preserved, we are without the means of forming an opinion of his eloquence, except from the statements of the ancients. It was highly ornamented, flowery, and even more Asiatic in its character than that of Cicero. His style was full of animation, and his composition was extremely polished. Hortensius also cultivated poetry with success. (Ovid. *Trist.* ii. 441; *Aul. Gell.* xix. 9. See Sallier, *Recherches sur la Vie de Q. Hort.* in the *Mém. de l'Acad. des Inscript.* vi. 500. Luzac. *Specimen historic. jurisdic. de Q. Hort. oratore*, Lugd. Bat. 1810. *Tiraboschi Storia della Litterat. Italiana*, iii. 2.)

HORTICULTURE.

Introduction.

Horticulture is that branch of rural economy which consists in the formation and culture of Gardens. Its results are culinary vegetables, fruits, and flowers. On one side it is allied to Agriculture, from which, however, it is distinguished by the nature of its products, and by the smaller extent and greater complexity of its operations; on the other side, in its processes of embellishment, it approaches the arts of the Landscape Artist and the Forester, from which, however, it also retires in the comparative minuteness of its details. Respecting the former of these departments of rural art, considered as distinct from Horticulture, information may be obtained in the article on Gardening.

Like other arts, Horticulture borrows its principles from the general sciences. To Botany it is beholden for the facts and theories of vegetable physiology; to Chemistry for assistance in reference to soils, manures, and artificial heat; and to Meteorology for a knowledge of many circumstances which very materially affect the labours of the gardener. On these subjects, with which the philosophical horticulturist will not fail to make himself familiar, we refer to the various scientific articles in this Encyclopædia. It is very desirable that such information should be extensively diffused among *practical* men; as it is only from this quarter that much improvement, in our present state of knowledge, can be expected. Truth, however, obliges us to admit, that gardening has been most successfully practised, when treated as an empirical art. Few of those who are minutely conversant with its numerous manipulations have undergone such an intellectual training as to enable them to wield general principles with effect. Many who are not inexpert or unsuccessful while they follow the routine practice (a practice, be it remembered, founded on long experience) egregiously fail, when, with imperfect information, or ill-advised ingenuity, they endeavour to strike out new paths for themselves. The object of the art, too, limits the application of the deductions of science. Its whole business consists in the imitation of Nature, whose processes may indeed be, in some measure, originated, as when a seed is inserted in the ground, or modified, as in the artificial training of fruit-trees, but which may not be entirely controlled, much less counteracted. The principle of vegetable life will not endure interference beyond a certain point, and our theoretical views should be so directed as to interfere with it as little as possible. Observation and experiment are the grand means by which the art has arrived at its present state of advancement: at the same time it is obvious, that an enlarged acquaintance with science will aid us in imitating the processes of nature, will guide the hand of experiment, suggest contrivances, and enable us to guard against error; and above all, will tend to dispel those prejudices which practitioners in the empirical arts are so prone to cherish.

Gardening, Mr Walpole observes, was probably one of the first arts which succeeded to that of building houses, and naturally attended property and individual possession. Culinary, and afterwards medicinal herbs, were objects in request by every head of a family; and it became convenient to have them within reach, without searching for them in woods, in meadows, or on mountains, as they were wanted. Separate enclosures for rearing herbs were soon found expedient. Fruits were in the same predicament; and those most in use, or the cultivation of which required particular attention, must early have entered into and extended the domestic enclosure. Such may be deemed the leading heads of a conjectural history of the art; and indeed, if we would ascend into remote antiquity, we can have recourse only to conjecture, for although, in the Sacred Writings, and in the earliest profane authors, allusions to gardens occur, little is told us either of their productions or their culture. At the close of the Roman commonwealth, the catalogue of fruits had become considerable, the principles of grafting and pruning were understood and practised, and shortly afterwards, even artificial heat seems to have been partially employed. With the decline of the empire, horticulture also declined or became stationary; but at the revival of learning, it arose from the slumber of the dark ages, encumbered, it is true, by the dreams of the alchymists, the restrictions of unlucky days, and the imaginary effects of lunar influence. From these fetters it was ere long emancipated by the diffusion of knowledge, and it has hitherto kept pace with the general improvement of society. Modified by climate and other circumstances in different countries, its advancement has been various; but nowhere has it made greater progress than amongst ourselves. Introduced into England at an early period, gardening became conspicuous in the reign of Henry VIII. and his immediate successors, and met with considerable attention during the reigns of the Stuarts. In the first half of the eighteenth century, Miller, Switzer, and others, laboured with success in improving the operations, and unfolding the principles, of the art; and these were succeeded by Abercrombie, Speechly, and a host of writers, who added greatly to our stores of knowledge. In 1805 was established the Horticultural Society of London, which was soon followed by the institution of the Caledonian Horticultural Society at Edinburgh; and in their train have sprung up a multitude of provincial gardening societies, all of which have given an impulse to the public mind, and stimulated the exertions of individuals. Experimental gardens have been formed, in which, amongst other things, the important work of distinguishing and classifying the numerous varieties of our hardy fruits has been zealously prosecuted. The mass of information now collected is immense, and the labour expended in its diffusion unwearied. Judging from the literature of the day, and passing downward from the sumptuous Transactions of the metropolitan Society, through the numerous periodicals, to the penny information for the people, we shall scarcely find any art, however nationally important, which receives more attention, or on which the liberality of the wealthy is more abundantly bestowed. The public nursery-gardens, too, both at London and elsewhere, establishments intimately connected with our subject, and which, in a manufacturing nation, are not the least wonderful amongst the applications of skill and capital, prove the extent and perfection to which gardening has advanced. Although, however, there is not, perhaps, in the annals of invention, a chapter of higher interest than the history of Horticulture, our limits do not permit us to enter further into details: we must therefore refer to Loudon's *Encyclopædia of Gardening*, a work which, for minuteness of exposition, and copiousness of illustration, is unrivalled amongst the didactic treatises of our times.

We intend to confine our attention almost exclusively to the horticulture of Great Britain, and we shall endeavour to give such an exhibition of its practice as may suit the middle districts of the island. The objects of culture are so numerous, the operations so varied, and the materials so copious, that, in presenting what can claim only the character of a sketch of our subject, it will be necessary to follow a plan of selection. It would be unprofitable to describe all the methods of culture in practice; we shall therefore notice such only as are deemed the best.

The subject naturally divides itself into the Fruit, the Kitchen, and the Flower Garden; but as the first two generally occupy the same locality, or are intermingled with each other, and as every thing connected with their formation is inseparably involved, we shall, to some extent, take them together. Then will follow the Flower-Garden; and by way of conclusion to the whole, a short Calendar.

FRUIT AND KITCHEN GARDEN.

In this department are cultivated the articles which are necessary for the supply of the kitchen and the dessert table. It is inclosed within walls, not only for the sake of security and general shelter, but, in our climate, as affording the means of cultivating the finer fruits, by training the trees close to the walls. It is furnished with hot-houses, melon-frames, and similar contrivances, by which the fruits of other climates are subjected to an artificially increased temperature, and thus brought to maturity. The size of a walled garden ought evidently to bear some proportion to the splendour of the mansion-house of which it is an appendage, to the extent of the park, and the means of the family. Where the demand is large, such a garden should comprehend from four to six acres. In many places this extent will not afford an adequate supply of culinary vegetables, but some of the bulkier crops, such as pease, potatoes, and turnips, may be grown in the exterior fields. From an acre and a half to three acres may be regarded as forming a respectable garden; but, within the limits already mentioned, it is better, in the first formation of a garden, to enclose too large a space than too small a one.

The productiveness of such an establishment will depend chiefly upon the natural fertility of the soil, and the eligibility of the situation, but also in a considerable degree upon the labour expended upon the culture. Where a garden is *underworked* (to use a gardener's phrase), the finer products must necessarily be scanty, for whatever requires care, requires time; and it not unfrequently happens that a gardener fails in some crop, not from defect of method or skill, but because he has not been able to overtake it, or has been obliged to make his preparations in a hurried and insufficient manner. All circumstances being favourable, a British garden is perhaps unrivalled in fertility by any cultivated spot in the world. A copious supply of esculents flows into the kitchen at all seasons; and after a rich abundance of fruit has been afforded during summer and autumn, the winter stores may be easily prolonged till the early forced fruits come again to the table.

We shall first treat of the general properties and appendages of the Fruit and Kitchen Garden.

Situation.—The position of the garden in relation to the mansion-house, properly belongs to the province of Landscape-Gardening, as it obviously should be in keeping with the general features of the park scenery. It may, however, be remarked, that, as a place of interest to every well-informed proprietor, it should be so near as to be conveniently accessible on foot, probably within little more than a quarter of a mile; while it should be so distant as to avoid the possibility of offence arising from gardening operations and the resort of workmen. A position on one side of the house is to be preferred, unless a much more eligible one occur in the rear. Wherever it be placed, it should be so masked by evergreen shrubs and trees, as not to be visible from the principal lawns, or from the walks in the shrubbery and flower-garden. If the surface of the domain be undulated, the garden is almost unavoidably seen from some point or other, and the *coup-d'œil* of the enclosure walls is apt to present the idea of a large box; an unpleasant impression, which should by all means be avoided or lessened by plantations judiciously placed.

Ground possessing a gentle inclination toward the south is desirable for a garden. On such a slope effectual draining is easily accomplished, and the greatest possible benefit is derived from the sun's rays. The lower part of a gentle declivity is perhaps to be preferred; but a very low situation should scarcely be chosen, as the subsoil is apt to be damp, fogs often brood over such spots, and frosts are more injurious there than on higher ground. It is beneficial to have an open exposure towards the east and west, so that the garden may enjoy the full benefit of the morning and evening sun.

Shelter is absolutely necessary; and that afforded by natural objects, such as rising grounds, is the best. Where this is wanting, its place should be supplied by masses of forest-trees, disposed at such a distance, however, as not to shade the wall-trees, perhaps not nearer than 150 feet. The purpose of such screens is to break the force of the winds; and as every situation is, in this respect, liable to some peculiarities occasioned by the general structure of the country, or by the reverberation of aërial currents from adjacent eminences, these peculiarities should be carefully observed and obviated. The idea that crowded plantations increase the warmth of a place is often fallacious; and, in the opinion of many, they do more harm than good, by encouraging blight. The trees employed may be of a varied character, but lime-tree, horse-chestnut, beech, sycamore, weeping birch, and the smooth-leaved wych elm, should prevail. There may also be a proportion of evergreen trees, such as firs, pines, hollies, and evergreen oaks. When these masses of wood are planted at the time the garden is formed, poplars, larches, and other fast-growing trees, should be thickly intermixed to act as temporary trees and nurses, which are afterwards to be weeded out, as the permanent trees more slowly advance to maturity.

A supply of *water* is equally necessary. Where a streamlet can be made to flow through the garden, and keep a central pond constantly full, it will conduce both to utility and amenity. If this cannot be effected, a pipe of sufficient caliber should be led from some neighbouring pond to the hot-houses, and to two or three different stations in the garden. Well or spring water should be exposed in tanks or reservoirs to the action of the sun and air, when it becomes comparatively soft and salubrious for plants. As rain water is found better than any other for this purpose, all that can be collected should be stored and kept for use.

Connected with the situation is the *approach* to the garden from without, a matter requiring some taste and contrivance. If possible, it should be from the south, when the range of glazed houses will be seen at once, and produce a pleasing effect. Sometimes a lateral entrance is very suitable, leading, it may be supposed, from the flower-garden through an intermediate shrubbery, and coming upon the hot-houses in flank. It is delightful to be introduced at once and by surprise into a Slip, as it is called, where on the one hand there is an extent of wall covered with luxuriant fruit-trees in full bearing, and on the other is displayed a rich collection of ornamental shrubs and large perennial border-flowers.

Form.—The form of a garden, it is obvious, must chiefly be determined by the nature of the situation and the taste of the proprietor. In general, gardens are either squares or oblongs, chiefly, it is presumed, because walls of this configuration contain the greatest space within the least perimeter, a result of very questionable value. They may be of any form, with this limitation, that attention should be paid to facilitating the transport of manures and garden products, for when the grounds are straggling, or complicated in structure, the labour of cultivation is much increased.

Exterior Fence.—Most gardens are encircled by an outer boundary, formed by a sunk wall or ha-ha, surmounted by an invisible wire fence to exclude hares, or by a hedge and paling. Occasionally this sunk wall is placed on the exterior of the screen plantations, and walks lead out among the trees, to give favourable views of the adjacent country. Although the interior garden receives its form from the walls, the ring fence and plantations may be adapted to the shape and surface of the ground. The spaces between the outer fence and the walls are, as already noticed, called *Slips*, and, where circumstances render it eligible, a considerable extent of ground is sometimes included, and appropriated to the culture of small fruits and vegetables. If possible, the gardener's house should be situate here, as being convenient for him, and as tending to scare depredators.

Walls.—For the production of the finer fruits, such as peaches, apricots, hardy grapes, and most of the delicate French and Flemish pears, the aid of walls is indispensable in our climate. Indeed, in the northern and higher parts of the country, where there is no walled garden, the dessert can seldom consist of more than small fruits, and ill-ripened apples and pears. So valuable in this respect are walls, that it is perhaps a matter of surprise that they have not been multiplied by the erection of slight and cheap structures, such as are common in the peach-gardens in France. The north wall having, in the interior, a south aspect, is of course appropriated to the more tender kinds of fruit-trees; here, it is generally estimated, they enjoy an increased temperature equal to 7° of south latitude; the east and west walls are set apart for fruits of a somewhat hardier character; while the inner face of the south wall, having a north aspect, is well adapted for retarding Morella cherries and currants.

The north wall is generally placed nearly perpendicular to the meridian, that is, so as to have the sun directly in front at 12 o'clock. Minute directions have indeed been given to make it face towards 11 or $11\frac{1}{2}$ A. M., on the ground that thus it would sooner meet the rays of the morning sun; but it does not appear that this arrangement has been the subject of direct experiment, and certainly the arguments, by which the superiority of this aspect is supported, are far from being satisfactory. The east and west walls are commonly placed at right-angles to that already mentioned, but they may follow the shape of the ground, and if this slope to the south, they descend with the declivity. The south enclosure wall, as affording on the outside a valuable aspect to the south, is deserving of particular attention. It is presumed that the walls are to be covered, both within and without, with trees trained *en espalier*.

Different portions of the enclosure wall are always built of different heights, and this variation of height is the more necessary, when the ground approaches to a level. In such a situation, and when the enclosure does not exceed two acres, the north wall may rise to the elevation of 14 feet; the walls on the east and west may be two feet lower, and the south wall need not exceed 10 feet. In larger gardens, the walls are generally made proportionally higher: on the north, perhaps 16 feet, on the east and west 14, and on the south 12. In several excellent Scottish gardens planned by Mr John Hay, such as that at Castle Semple, a piece of building is made to project diagonally outwards from the corners where the walls meet at right-angles. This projection is 16 or 17 feet in length. It serves to strengthen the fabric, and, at the same time, breaks the force of the winds which sweep around walled gardens.

Walls inclined to the horizon have been recommended by Desaguliers and others; but, independently of the theoretical objections which might be urged against them, and which, in actual practice, would probably counterbalance their supposed advantages, they must be extremely inconvenient from their bulk, or the space which they occupy; and hence they have never come into general use.

Bricks afford the best and the most kindly material for garden-walls. Being bad conductors of caloric, they accumulate heat; they do not retain moisture, and, by their numerous interstices, they furnish every facility for nailing in the twigs of the fruit-trees. Where freestone (that is, sandstone capable of being easily dressed) is abundant, the exterior wall is often formed of coursed masonry, and the interior is faced with bricks. The foundation should, if possible, be formed of stone. Whinstone (that is, either the greenstone or the basalt of mineralogists) forms an excellent material for fruit-walls. It is susceptible of a neat hammer-dressing; it does not readily imbibe moisture, and therefore is not much cooled by evaporation; and being of a very dark colour, it absorbs more solar heat during sunshine than a lighter surface, while at night the radiation from both is nearly the same. Part of the principal fruit-wall of the Experimental Garden at Edinburgh is built of greenstone; and the plants trained against it have evinced, by their growth, that they enjoy a superior temperature.

For the preservation of the walls, a coping is necessary; and it seems a matter of indifference whether it be formed of stones with a rounded surface, or of flat pavement, or of tiles. Probably it should not project more than an inch, though some contend for a larger measure, on the ground of its preventing to some extent the radiation of heat from the tree towards the sky in clear nights, and affording shelter from the perpendicular deposition of dew. Temporary copings of wood are often adopted, and are found to answer every good purpose. They are put on in spring, to protect the tender blossom and embryo fruit from the hoarfrosts, and when danger is past are removed, to give free access to the genial showers and sunshine of summer and autumn.

Hot Walls.—A considerable proportion of the walls of every good garden, especially in the north, should be constructed with flues, to supply the means of applying artificial heat. The additional expense is trifling; and in colder situations, the aid of this species of wall is nearly indispensable for the regular ripening of peaches, grapes, and figs. The application of fire-heat for a few weeks in spring will secure the setting of the fruit, and the same operation continued for a short time in autumn will suffice to ripen it, and also to prepare the young wood for the next year. The flues may be about twenty inches deep, and should make as many horizontal turns as the height of the wall will allow. One furnace will be enough for a surface fifty feet in length. When the boundary walls do not furnish room sufficient for the production of the finer fruits, one or perhaps two middle walls are built across the garden from east to west, of the same height as the side walls, to which they nearly approach. They are generally flued, and are sometimes covered, on their southern aspect, with glazed frames, either fixed or moveable. These cross walls add greatly to the capabilities of a fruit-garden, and are useful in affording additional shelter to the small fruits and crops of vegetables.

Espalier-Rails.—Subsidiary to walls as a means of training fruit-trees, espalier rails were formerly much employed, and they still prevail in many parts of the country. In their simplest form, they are merely a row of slender stakes of ash or Spanish chestnut, driven into the ground, and connected by a slight rod or fillet at top. In some gardens, the perpendicular rods are fastened into two horizontal rails, supported by strong posts, which are battened into stones. Cast-iron rails have also been proposed. The frame-work is sometimes inclined to the horizon, and sometimes flat like a table, which last, when there is room, is perhaps the best arrangement. Espalier rails, especially the more elaborate sorts, are expensive and formal, and therefore in many instances have given place to dwarf standard trees, which are equally productive, and far more elegant in their appearance.

Soils.—It is of great importance that the ground selected for a garden should be naturally of a good quality. A hazel-coloured loam, of a light or sandy texture, is well adapted for most crops, whether of fruits or culinary vegetables. As it is more easy to render a light soil sufficiently retentive, than to make a tenacious clay sufficiently porous, a light soil is preferable to one which is excessively stiff and heavy. It is advantageous to possess a variety of soils; and if the garden be on a slope, it will often be practicable to render the upper part light and dry, while the lower remains of a heavier and damper nature. The soil should be good to the depth of two feet, and any necessary additional deepening by manures or otherwise, should not be neglected. The nature of the subsoil demands particular attention. If it be strongly impregnated with metallic substances, or composed of cold till, it will prove pernicious to the roots of fruit-trees, and will scarcely admit of a remedy. A decomposing rock, or a bed of sand, is preferable. Perhaps the best of all is a dry bed of clay, overlying sandstone, which crops out within the enclosure. If the inferior strata be retentive, and if water lodge in any part of the garden, draining should be carefully executed, so as to carry off the superfluous moisture.

Preparatory to the distribution of the several parts of a garden, it is proper that the ground be trenched to the depth of two feet at least; but the deeper the better. In this operation all stones larger than a man's fist are taken out, and all roots of trees, and of perennial weeds, are carefully extracted and cleared away. When the soil is not tolerably good to the depth of two feet, it will often be proper to remove a portion of the subsoil; and its place should be made up by a proportional quantity of turf or fresh loam from the fields. If the subsoil be gravel, and the upper layer sandy, the additional earth should be clayey loam, or the scourings of ditches; but if the original body of soil be of a compact texture, the materials introduced should be mixed with sand, marl, and other light opening substances. When the whole ground has been thus treated, a moderate liming will, in general, be useful. After this, supposing the work to have occupied most of the summer, the whole may be laid up in ridges, to expose as great a surface as possible to the action of the winter's frost. The draining, trenching, and other operations here recommended, will unavoidably be attended with considerable expense, and this expense will not immediately be followed by any perceptible beneficial result. The lapse of a few years, however, will develope the vast advantages of such a mode of procedure, which, if it have been neglected at first, cannot be practised at a subsequent period but with indifferent success, and not without a great increase of care and labour.

Manures.—In enumerating the general appendages of gardens, it may be proper to say something of manures, but we do not consider it necessary to enter into minute details on this subject. Where there are extensive melon grounds, an abundance of stable and other litter is required; and this substance, in its partially decomposed state, as afforded by exhausted hotbeds, supplies a manure well adapted to aid the processes of vegetation. Decayed leaves, which are plentiful where there are extensive pleasure-grounds, also form an excellent manure for many purposes. Some practical men prefer composts to simple dungs, or such substances as have undergone fermentation. For fruit-trees turf from rich pastures, mixed with vegetable earth, is perhaps the best stimulant which can be applied. It is questionable whether any sort of trees are permanently benefited by the application of crude manures to their roots; and it is certain that many have been irremediably injured by this practice. But whatever caution may be necessary in their use, the prudent horticulturist will find it expedient to pay particular attention to the collection of manures. He cannot go on long without them; for ground which is exhausted by continual cropping, requires to be continually repaired.

Internal Arrangement of Gardens.—A considerable portion of the north wall, or of the cross-wall, is covered in front with glazed structures, called hothouses, or forcing houses. To these the houses for ornamental plants are sometimes attached; but the last are more appropriately situate in the flower garden, when that forms a separate department. It is well, however, that every other thing connected with the forcing, whether of fruits or flowers, should be concentrated in one place. The melonry and other smaller pine-pits, should occupy some well-sheltered spot in the slips, or on one side of the garden, and, if possible, in the neighbourhood of the stable-yard. Adjoining to this may be found a suitable site for the compost ground, in which various kinds of soils may be kept in store, and composts may be prepared.

Extensive gardens, in exposed situations, are often divided into compartments by hedges, so disposed as to break the force of winds. Where these are required to be lofty yet narrow, holly, yew, or beech is preferred; but if space be no object, common laurel-bay is one of the most beautiful plants that can be employed for this purpose. Smaller hedges may be formed of evergreen privet, or of tree-box. These subordinate divisions, though often neglected, are worthy of attention; for, in addition to shelter, they furnish shade, which, at certain seasons, is peculiarly valuable.

The laying out of the area of the garden in walks, borders, and compartments, may be regulated very much by the shape of the ground, and the taste of the owner. In general, a gravel walk six or eight feet broad, is led quite around the garden, both within and without the walls. A walk of similar dimensions is often constructed in the centre of the garden in the direction of the glazed houses, and this is sometimes crossed by another at right-angles. At times these walks are led diagonally from the corners. The space between the wall and the walk that skirts it, is called the wall-border, and is commonly from fifteen to twenty feet broad. On the interior of the walk there is usually another border five or six feet broad, which is generally occupied by fruit-trees trained to espalier rails, or by dwarf standard trees. The middle part of the garden is divided into rectangular compartments for the raising of the various culinary crops. These compartments may be divided by rows of moderate-sized fruit-trees, or of gooseberry and currant bushes. It is advantageous to have several small beds, in which to cultivate the less bulky articles, such as basil, sage, tarragon, &c. which, in large spaces, are apt to be overlooked or neglected.

Wall-Borders.—The preparation of borders for fruit-trees is a matter of the utmost importance, and no pains should be spared in this essential operation. Where borders are not in good condition, the care and toil of the most experienced gardener will avail but little to the production of fruit. The first object is effectual draining. The next, if the subsoil be indifferent, is the formation of a bottom impervious to the roots of trees. This is sometimes done with stone-shivers and lime-rubbish, or with coal-ashes and clay, compacted by treading with the feet, and beating with the back of a spade. Loudon recommends successive layers an inch thick of clean gravel, pulverized earth, and then gravel, well watered and firmly compressed by means of a heavy roller. Good soil to the depth of two feet and a half, or three feet, is placed over this impervious bottom. Three-fourths rich loam, and one-fourth light sandy earth, form a mixture congenial to the generality of fruit-trees, In selecting the soil, regard may be had to the particular trees which are to cover each portion of the wall. Thus a heavy soil may be allotted to pears and plums; loam of a medium character, inclining to be strong, to peaches; and a lighter earth for cherries and figs. Above all, care should be taken to render the borders sufficiently rich and substantial. Whilst every skilful horticulturist can in various ways reduce the luxuriance of his trees, nothing can compensate for extreme poverty in the soil. The same principle will dictate moderation in cropping wall borders with culinary vegetables; a practice in which gardeners are apt to exceed, from a desire to furnish very early crops of pease, turnips, cabbage, or potatoes.

Orchards.—In most large gardens dwarf standard trees may be planted, sufficient to afford a supply of fruit for an ordinary family. Where this is not the case, it is desirable that there should be a separate orchard. A situation similar to that of a garden, and the same preparatory operations, are necessary: but a simple hedge will, in most situations, suffice for a fence. The trees may here be on free stocks and high standards, and the taller growing pears and apples are best suited for a large orchard. Thorseby in his Diary, under date of March 1702, mentions, as a novelty, an orchard "kept in the new order of dwarf trees," evidently intimating that dwarf standards were introduced from Holland by the Prince of Orange at the time of the Revolution. When an additional supply of culinary vegetables is required, they may be cultivated in the orchard; and then the trees should be planted in rows, with considerable intervals between the rows, otherwise the close quincunx order is preferable. In any circumstances, the trees should not be choked up with currant and gooseberry bushes, as is common in market gardens. On the margin of the orchard may be planted Walnuts, Chestnuts, Filberds, and any other fruit-trees less commonly cultivated, or the fruit of which is not much in demand. The whole should be effectually screened from the prevailing winds, by rows of forest trees, at a sufficient distance, however, to prevent shading, or the robbing of the soil.

FRUIT GARDEN.

We shall first direct our attention to the culture of hardy fruits, or of such as, in our climate, do not, to an extensive degree, require the assistance of artificial heat. But before proceeding to a minute detail of the management of the different varieties, it may be proper to attend to some of the operations which are common to all.

Preliminary Operations.

These may be classed under the heads Propagation, Planting, Training, and the Protection of Blossom.

Propagation by Seed.—Although fruit-trees are furnished with all the natural means of reproduction, it is not in general expedient to attempt to propagate them by the sowing of seed. This method is found to be equally tedious and precarious, requiring the labour of a good many years, and very seldom producing an exact copy of the fruits from which the seeds are taken. All our present admired fruits are seminal varieties obtained from the wild inhabitants of the forests; they have been trained into an artificial condition; and when sown, seem to have a tendency to resume their original constitution. In the peach-orchards of America, for instance, which are planted with the kernels of choice sorts, there are seldom more than a few trees affording fruit fit for the table: the produce of the majority is so worthless, that it is employed for feeding the hogs. Notwithstanding this embarrassing circumstance, there are some considerations which render this mode of propagation at once interesting and important to horticulturists. It is the only way by which we can procure new kinds to supply the place of those which are falling into decay; and it is a great means of adapting the tender sorts to the rigour of our climate. It is well known that some of the favourite cider apples of the seventeenth century have become extinct, and others are fast verging into decrepitude; and hence the conclusion has been drawn, that all our present fruits, as they are artificial in their constitution, are also limited in their duration. Each variety springing from an individual at first, however extended by grafting or budding, partakes of the qualities of the individual: and where the original is old, there is inherent in the derivatives the tendency to decay incident to old age. It is assumed that all the individual trees of any given variety, such as the golden pippin, or the grey leadington, are in a lax sense equivalent to *one individual.* By careful management, the health and life of this composite individual may be prolonged; and grafts inserted into vigorous stocks, and nursed in favourable situations, may long survive their parent tree; still there is a sure progress towards extinction, and the only renewal of the individual, the only true reproduction, is by sowing seed. It is admitted by those who have paid attention to the subject, that this curious principle of vegetable economy holds true, at least so far as regards fruit-trees.

Mr Knight, to whom this ingenious theory is due, conceived the idea of supplying the lack of old varieties by semination. It further occurred to him, that advantage might be taken of that tendency which plants exhibit on repeated sowings, to adapt themselves to the climates in which they are raised, so that trees of warmer countries may thus become habituated to colder regions. He therefore devoted much of his attention to the production of improved and robust varieties; and his zeal and labours have been rewarded by the Acton Scott Peach, the Ingestrie and Downton Apples, and many others, in almost every sort of hardy fruit. Mr Knight entertained the opinion, deduced, we may presume, from experiment, that more is to be expected from hybrid varieties, than from the mere reproduction of old kinds; he therefore had recourse to the nice operation of dusting the pollen of one kind on the pistil of another. He opened the unexpanded blossom of the variety destined to be the female parent of the expected progeny, and, with a pair of small-pointed scissors, cut away all the stamens, while the anthers were yet unripe, taking care to leave the style and the stigma uninjured. When the female blossom, thus prepared, naturally expanded, the full blown blossoms of the other variety destined to be the male parent were applied. Mr Knight has often remarked in the progeny a strong prevalence of the constitution and habits of the female parent: in this country, therefore, in experimenting on pears, the pollen of the more delicate French kinds, such as crasanne and chaumontelle, should be dusted upon the flowers (always deprived of stamens) of the muirfowl egg, the grey achan, the green yair, or others, that are hardy, or of British origin.

As this is a subject of interest, we may state some of the precautions adopted by Mr Knight and his followers, in conducting their experiments. It is, in the first place, a rule to employ seeds of the finest kinds of fruit, and to take them from the largest, ripest, and best-flavoured specimens of that fruit. When Mr Knight wished to procure some of the old apples in a healthy and renovated state, he prepared stocks of such good sorts as could be propagated from cuttings, he planted them against a south wall in rich soil, and then grafted them with the kind required. In the following winter the young trees were taken up, their roots retrenched, and then replanted in the same place, by which mode of treatment they were thrown into bearing when only two years old. Not more than a couple of apples were allowed to remain on each tree, and these in consequence attained a larger size and more perfect maturity. The seeds were then sown, in the hope of procuring an equally excellent and more vigorous offspring. In the case of cross-impregnation, every seed, though taken from the same fruit, produces a different variety, and these varieties, as might be anticipated, prove to be of very various merit. In general those seeds are to be preferred which are plump and round. An estimate of the value of the seedlings may be formed, even during the first summer of their growth, from the resemblance they bear to those of highly cultivated and approved trees. The leaves of the promising seedlings improve in character, becoming thicker, rounder, and more downy every season. Those whose buds in the annual wood are full and prominent, generally prove more productive than those whose buds are small and shrunk into the bark. Early flowering and hardy blossoms are desirable characters. It has been observed, that even after a seedling tree has commenced bearing, its fruit has a tendency to improve as the tree itself acquires vigour, so that, if, in the first season, there is any considerable promise, a great improvement may be expected in succeeding years.

The slowness with which seedlings reach the bearing state, has been the subject of complaint among horticulturists, and indeed is the principal reason why this mode of propagation has not been more frequently practised. According to Mr Knight, the pear requires from twelve to eighteen years to reach the age of puberty; the apple from five to twelve or thirteen years; the plum and cherry four or five; the vine three or four; the raspberry two years. The peach, he found to bear in two, three, or four years. This period, however, must depend on the soil, situation, and mode of culture. In the warm and highly manured garden of M. Van Mons at Brussels, (called Pepinière de la Fidélité), seedling pear-trees produced fruit in considerable quantities in the sixth and seventh summers. The great means of accelerating the epoch of bearing, seems to be, to make the trees grow vigorously when young. Crude manures are indeed to be avoided; but vegetable earth, and, above all, a liberal supply of rotted turf, are wholesome and excellent stimulants. The seed-bed, and the ground on which the seedlings are transplanted, should be extremely well worked and comminuted with the spade; and should not be too much exposed to the parching rays of the sun, and the action of the wind. Great care ought to be taken to prevent the young plants from becoming stunted. In pruning, the small twigs in the interior should be removed, so as to relieve the tree from the bushy appearance which it frequently assumes. It has been recommended to transfer cions and buds of promising individuals into other trees in a bearing state. This is peculiarly advantageous with respect to the peach and other stone fruits, as it both hastens the period of puberty, and economises the space which must be occupied on the wall.

Propagation by Cuttings.—Gooseberries, currants, figs, vines, and some others, are increased by means of cuttings. An annual shoot is taken off, along with a thin slice, or *heel*, as it is called, of the former year's wood, which is found to facilitate the production of roots. The cuttings are placed firmly in the soil, at various depths, according to their length, the buds or eyes which would thus come beneath the surface having been previously removed. Vines are sometimes propagated from small pieces of shoots having a single bud: when they have to be transmitted to a distance, an inch in length may suffice. Most of the codlin apples may be increased by cuttings; and even large branches of those which produce *burs*, may be planted at once, with success. In all deciduous trees, the operation is most advantageously performed in winter.

Propagation by Layers.—This is not much resorted to in the fruit garden. It is occasionally employed as the means of dwarfing trees. "Laying," says Mr Lindley, "is nothing but striking from cuttings which are still allowed to maintain their connexion with the mother plant by means of a portion at least of their stem." The operation is performed by bending down a branch to the earth, and pinning it there with pegs. A few inches from the extremity a notch or slit is cut upwards, generally from the insertion of a bud. Sometimes the shoot is pierced with a number of holes; a wire is bound round it; or even a ring of bark is removed. The object of these expedients is to retard the descending sap, and thus to promote the formation of radicles, or young roots. This is also aided by bending the branch upward from the point at which the roots are wanted; and the whole branch, except a few buds at the extremity, is covered with soil. The seasons best fitted for these operations, are early in spring and about midsummer, that is, before the sap begins to flow, and after it has completely ascended. One whole summer, sometimes two summers, must elapse before the layers be fully rooted.

Propagation by Grafting.—When a shoot or young branch of one tree is inserted into the stem or branch of another, and, by the influence of vegetation, is made to coalesce with it, the process is termed grafting. In this manner apple and pear trees, sometimes plum and cherry trees, are propagated. Our attention must be directed to the *stocks* into which the shoots or cions, as they are called, are inserted; to the *cions* themselves, and to the *mechanical operations* employed in grafting.

The *stock* should be of the same *genus*, or, at least, of close affinity in natural family, to which the graft belongs. The following are the principal kinds of stocks, including, by anticipation, such as are used in budding. For *apples*, seedlings of the crab apple, layers of the doucin or paradise, and of the codlins, with cuttings of the bur-knot varieties. For *pears*, seedlings of the common, and wilding pear; with seedlings or layers of quince. For *plums*, seedlings of any of the common sorts, particularly the muscle, the Brussels, and the Brompton; also the Bullace plum. For *cherries*, seedlings of the small black cherry or gean, Prunus Avium; and, for dwarfing, P. Mahaleb. For *apricots*, seedlings of the wilding apricot, with the muscle and Brussels plums. For *peaches* and *nectarines*, seedlings of the muscle, white pear-plum, and Damas noir plum, the almond, and the wilding peach.

Stocks are commonly divided into two classes, viz. *free-stocks* and *dwarfing stocks*. The former consist of seedling plants which naturally attain to the same size as the trees from which the cions are taken. The latter are plants of diminutive growth, either varieties of the same species, or species of the same genus as the cion, which have a tendency to lessen the expansion of the engrafted tree. The Paradise or Doucin is the dwarfing stock for apples, the Quince for pears, the Bullace for plums, and Prunus Mahaleb for cherries. The nature of the soil, in which the grafted trees are destined to grow, should also have weight in determining the choice of stocks. When the garden is naturally moist, it is proper to graft pears on the quince, because this plant agrees with a moist soil, and at the same time serves to check the luxuriance thereby produced. In France, peaches are commonly budded on almond stocks, to adapt them to the dry soils of that country. The seeds from which stocks are to be raised, are generally sown in beds in March; but the germination of some kinds is promoted by placing the seed, for a time, in moist sand in a greenhouse. Next season the seedlings are transplanted into nursery rows, in which they are allowed to reach the size necessary for the various forms of fruit-trees hereafter to be mentioned.

The *cion* is always a portion of the wood of the preceding year. As the diseases incident to fruit-trees are transmitted by this mode of propagation, it is desirable that the parents should be as healthy as possible. In the shy-bear-

Fruit Garden.

ing kinds, it has been found beneficial to select shoots from the fruitful branches. The cions should be taken off some weeks before they are wanted, and half-buried in the earth, as it is conducive to success that the stock should, in forwardness of vegetation, be somewhat in advance of the graft. During winter, grafts may be brought from America, or from the Continent of Europe, if carefully wrapped up in hypnum-moss. If they have been six weeks or two months separated from the parent plant, they should be grafted low on the stock, and the earth should be ridged up around them, leaving only one bud of the cion above ground. Out of forty cions of new Flemish pears, procured by the Caledonian Horticultural Society from Brussels and Louvain, and treated in this way, only one failed.

Success in *grafting* depends almost entirely on accurately applying the inner bark of the cion to the inner bark of the stock, so that the sap may pass freely from the one to the other. They are therefore fitted together and held fast by a slight bandage of matting. To lessen evaporation, a portion of ductile clay is moulded around the place of junction, and is retained until it appears, from the developement of leaves, that the operation has succeeded. The best season for grafting is the month of March; but it may be commenced as soon as the sap in the stock is fairly in motion, and may be continued during the first part of April.

The most usual mode of grafting is called *whip-grafting*, or *tongue-grafting*, represented in Plate CCXCIII., Fig. 8, *a*, *a′*. The top of the stock and the base of the cion are cut off obliquely at corresponding angles, as nearly as can be guessed by the eye; the tip of the stock is then cut off horizontally; next a slit is made downwards in the centre of the sloping face of the stock, and a corresponding slit upwards in the corresponding face of the cion. The tongue or upper part of this sloping base is then inserted into the cleft of the cion, and so adjusted that the inner bark may unite neatly and exactly on one side. The junction is then tied up and covered with clay. Several other methods may be mentioned, such as *cleft-grafting*, Plate CCXCIII., Fig. 8, *b*, *b′*, in which the cion is sloped at the base, and inserted like a wedge into a cleft in the stock. *Side-grafting*, Plate CCXCIII., Fig. 8, *d*, *d′*, which resembles whip-grafting, but is performed on the side of the stock without heading it down. *Crown-grafting*, Plate CCXCIII., Fig. 8, *c*, *c′*, in which the cion is inserted between the bark and the wood. *Grafting by approach*, or *inarching*, also resembling whip-grafting, but the cion remains attached to the parent plant. Plate CCXCIII., Fig. 8, *e*, *e′*.

It is evident that the method of performing the operation may be diversified to a great extent. The late M. Thouin of Paris described, in the Annales du Museum, nearly fifty *greffes*, but little practical utility results from such nice distinctions. It is of greater importance that the horticulturist should be expert in the manipulation of the more common forms, such as those above enumerated. An extensive fruit-garden requires a frequent repetition of the operation, in order to secure proper kinds, and productive branches. At Dalkeith Park, Mr Macdonald, the excellent gardener officiating there, annually inserts on his established trees numerous grafts, and by this means is enabled to overcome the disadvantages of a somewhat unfavourable situation, and to obtain abundant crops of large and beautiful fruit.

Propagation by Budding.—Most kinds of fruit-trees may be propagated by budding; and there are some, such as peaches and apricots, which can scarcely be multiplied in any other manner. It consists in removing a bud with a portion of the bark from one tree, and inserting it in a slit of the bark of another tree. The season for performing this operation is in July or August, when the buds destined for the following year are completely formed in the axils of the leaves, and when the portion of bark parts freely from the wood beneath. The buds to be preferred are those on the middle of a young shoot. There are many forms of budding, but that which is simplest, and is generally practised in this country, called *Shield-budding*, need alone be described. The operator should be provided with a budding-knife, in which the cutting edge of the blade is rounded off at the point, and which has a thin ivory or bone handle, like a paper-folder, for raising the bark of the stock. A horizontal or transverse incision is made in the bark quite down to the wood, and from this incision a perpendicular slit is drawn downwards, to the extent of perhaps an inch. The slit has now a resemblance to the letter T (see Plate CCXCIII., Fig. 8, *f*, *f′*, *f″*); a bud is then cut from the tree wished to be propagated, having a portion of the wood attached to it, so that the whole may be an inch and a half long. The bit of wood is then gently withdrawn, care being taken that the bud adhere wholly to the bark or shield, as it is called. The bark on each side of the perpendicular slit being cautiously opened with the handle of the knife, the bud and shield are inserted. The upper tip of the shield is cut off horizontally, and brought neatly to fit the bark of the stock at the transverse incision. Slight ties of moist bass-matting are then applied. In about a month or six weeks the ligatures may be taken away, when, if the operation have been successful, the bud will be fresh and full, and the shield firmly united to the wood. Next spring a strong shoot is thrown out, and to this the stock is headed down in the course of the summer.

Planting.—After propagation, the next care is to transfer the young trees to those places, whether in the open air or against the wall, where they are to remain. It is of some importance that these situations should be considerately selected; for although all fruit-trees admit of repeated transplantation at a subsequent period, they seldom fail to exhibit injurious effects from it. Planting may be performed at any time in the beginning of winter, and in the early spring months; but it is considered that the most advantageous seasons are immediately after the fall of the leaf in autumn, and before the ascent of the sap in spring. The trees should be carefully lifted from the nursery lines, avoiding the mutilation or bruising of the roots; and, to prevent the desiccation of the fibres, they should be planted as soon as possible after being lifted. When they have to be carried to a distance, the roots should be enveloped in moist hypnum-moss. In the ground, which is presumed to have been previously trenched or otherwise prepared, pits or holes are formed, and the soil is finely pulverized; and in these the trees are placed, their roots being spread out and intermingled with the earth. Shallow planting is strongly recommended; two or three inches of soil being in general a sufficient covering. On filling up the hole, a surface of at least an equal size is *mulched*, that is, covered with dung or litter, so as to restrain evaporation, and preserve moisture. In the case of wall-trees, a space of five or six inches is usually left between the stem at the insertion of the roots and the wall, to allow for the effects of growth. To young standard trees stakes are added, to prevent their roots being ruptured by wind-waving. During the dry weather of the first summer, the trees should be watered from time to time as occasion requires.

The selection and distribution of the different kinds of fruit-trees is an important and interesting point in the formation of a garden. Regard must necessarily be had to local situation and climate, as the selection ought manifestly to be different for a garden in the south-west of England, and for one in Yorkshire or Scotland; for one near the level of the sea, and for another elevated several hundred feet. The best walls, having a south or south-east aspect, are dedicated to the grape-vine, the fig-tree, the peach, and apricot. The finer varieties of French and Flemish pears

Fruit Garden.

require and deserve a good aspect, as also the early sorts of cherries. The later cherries, and the generality of plums, succeed very well either on an east or west aspect. In Scotland, the mulberry requires the protection of a wall, and several of the finer apples do not arrive at perfection without it.

The wall-trees which are intended to be permanent are called *dwarfs*, from their being grafted near the ground. Between each of these, trees with tall stems, called *riders* in Scotland, are planted as temporary occupants of the upper part of the wall. The riders should always be five or six years trained in the nursery, in order that when planted out they may come into bearing as speedily as possible. The distances at which the permanent trees are planted is to be regulated by the known mode of growth of the different sorts, and by the height of the wall. When the walls are about twelve feet high, the following average distances have been recommended:—For vines, 10 or 12 feet; peach and nectarine trees, from 15 to 20 feet; fig-trees, 20 feet at least; apricots, from 15 to 24 feet; plums and cherries, from 15 to 20 feet; pear-trees, 20 feet if on quince stocks, and 30 feet on free stocks; apple-trees, 12 feet if on paradise stocks, and 15 to 25 feet on free stocks. Where the walls are only seven or eight feet high, the distance should be increased by nearly one-fourth, as in this case the want of height must be compensated by greater breadth.

Apples and pears make the best espalier-rail trees, especially in Scotland. These should be of the more robust sorts, and should be planted at the distance of 15 or 20 feet. Cherries and plums are sometimes introduced into the espalier-rail row, but these succeed in those situations only where they would do equally well or better as standards.

In many excellent gardens, dwarf standards are preferred to espalier-rail trees. They are placed along the inner borders at 8 or 10 feet apart. When proper attention is paid to such trees, the effect is very pleasing, each being in itself a handsome object, and generally clothed with fine fruit. Where the situation is warm, and the climate favourable, a few of such of the finer pears as have hardy blossoms should be planted out in this form. Though they may fail to ripen in some seasons, they will often add greatly to the resources of the fruit-room, their produce being frequently superior in flavour to the fruit grown on walls.

Training.—Two functions belong to training,—that, namely, which modifies the form of the tree, and that which regulates the bearing wood, and consequently the supply of blossom. The latter, more accurately termed *pruning*, being of a varied character, will more properly fall to be considered when treating of the several fruits; at present we shall make a few remarks on the former. The essential properties of training are, that it should be simple, not requiring frequent amputation; that it should be appropriate to the growth of the tree; and that it should be such as to facilitate the production of fruit. The knife is the great instrument in training, and whoever can wield it skilfully, will have a perfect command over his trees: at the same time, it may be laid down as a maxim, that it should be used with some degree of reserve, as nothing is more prejudicial to the health and fruitfulness of all sorts of trees, than severe and injudicious cutting.

Training of Standards.—Orchard-trees are generally worked in the nurseries with stems five or six feet high. All that is necessary, in pruning trees of this sort, is merely to cut out the branches which cross or press upon one another. Bushy heads should be thinned out, and those which are too lax cut back. Three or four leading branches may be selected, to pass ere long into boughs, and form a handsome skeleton for the tree; but it is useless to be finical in this matter, as these branches will soon grow beyond the power of the pruner, and of any artificial system which he may adopt. Dwarf standards being more accessible, are more under the dominion of training. When worked on paradise stocks, they may be kept not much superior in size to gooseberry bushes, and in a state of abundant fruitfulness. The more fanciful Dutch modes of training apple-trees, in the cup-and-ball fashion, and after many other curious devices, have never been relished in Britain. In this country, they are generally allowed to grow *en buisson*, that is as bushes. For pears, the French forms, *en pyramide*, fig. 1, and *en quenouille*, fig. 2, are justly gaining ground.

Fig. 1.

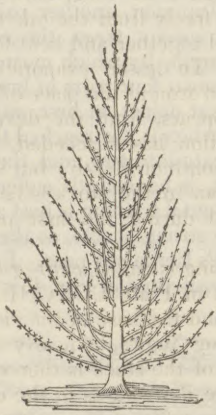

Fig. 2.

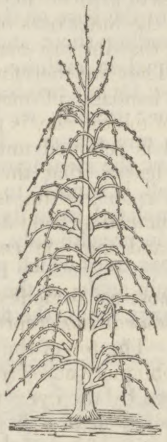


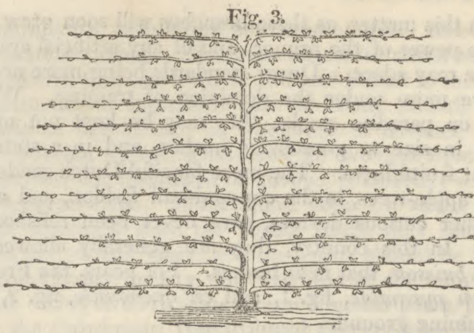
Training of Wall-Trees.—A fruit-tree planted against a wall is evidently in a constrained and artificial situation, from which it makes continual efforts to escape. Much attention is necessary to repress this tendency, which, were it permitted to act, would disfigure the tree, and neutralize the advantages of a wall, without imparting in their place the freedom of a standard in the open air. To be successful, the operator should be acquainted with the theory of vegetation, should study the mode of growth in different trees, and, above all, remember the purpose of all training, viz. the production of bearing wood.

One great difficulty is to preserve equilibrium in the growth of the several parts of the same tree: for the attainment of this object, excellent hints are to be found in the *Pomone Française:* we shall mention only two or three. A shoot will grow more vigorously whilst waving in the air, than when nailed close to the wall; a weak shoot should therefore be left free, whilst its stronger antagonist should be restrained. A shoot diverging slightly from the perpendicular, will, other things being equal, obtain a more copious supply of sap than one that is laid out horizontally, or is deflected downwards. A luxuriant shoot may be retarded for some time, by having its tender extremity pinched off, and thus allow a weaker brother to overtake it. By these and other expedients, which will suggest themselves to an attentive horticulturist, and by the prudent use of the knife, it will be easy to execute the following forms, which, on account of their simplicity and general excellence, we select out of many to be found detailed in works on gardening.

The *horizontal* form (fig. 3.) has long been a favourite in this country, having been strongly recommended in the excellent work of Mr Hitt. There is one principal ascending stem, from which the branches depart at right-angles, at intervals of ten inches or a foot. In trees of ordinary vigour, the vertical shoot is cut back every winter to within fourteen inches of the highest pair of branches: a number of shoots are produced in the beginning of each sum-

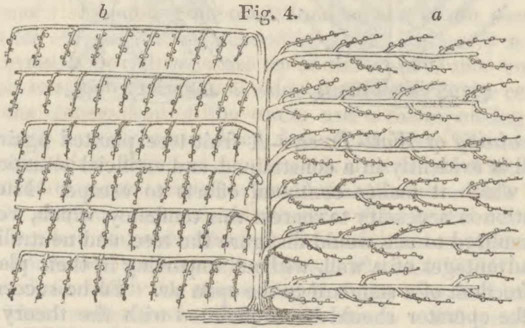
Fruit Garden.

Fig. 3.



mer, out of which three are selected: one is trained in the original direction of the stem, and one on each side of it, parallel to the base of the wall. By pinching off the point of the leading shoot about midsummer, another pair may be obtained in autumn. In luxuriant trees, the vertical shoot may be left two feet in length, by which means, and by summer pruning, we have known four pairs of branches added in one season. The great object, at first, ought to be to draw the stem upwards: when it has reached the top of the wall, it is made to divaricate into two, and the tree, thus completed as to its height, is henceforth suffered to increase in breadth only. Horizontal training is best adapted to those trees which produee strong shoots, as the Ribston Pippin apple, or the Gansel's Bergamot pear. For the more twiggy kinds, the form represented in Fig. 4. is more suitable. In this the horizontal branches are eighteen or twenty inches distant, and the small shoots are trained in between them, either on both sides, as below letter *a* in the figure, or on the under side and downwards, as below *b*. This last is an excellent method of reclaiming neglected trees of this description. Every alternate branch being taken away, and the spurs cut off, the young shoots are trained in, and soon produce excellent fruit. It is rather singular that Thouin, in his account of the *Ecole d'Agriculture pratique du Muséum*, classes the horizontal form among *les tailles hêteroclites ou peu perfectionnées*, and says, that, in consequence of its invariably producing a *tête de saule*, that is, a hedge of young shoots at the top, it has been long since abandoned. From this remark, we must draw the conclusion, that in France the theory of training is in advance of the practice.

Fig. 4.



The other principal form is called *fan*-training. In this there is no leading stem, and the branches are arranged somewhat like the spokes of a fan. Fig 5. represents this shape as it commonly occurs in gardens. It is difficult to say how, in the case of apple and pear trees, this mode, though frequently adopted, is superior or even equal to the horizontal configuration: it is evident, that when the branches reach the top of the wall, where they must be cut short, a *tête de saule* is inevitable. It would be better to adopt the modification of the fan shape used for stone fruits (fig. 6); to establish a certain number of mother branches, and on these to form a series of subordinate members, chiefly composed of bearing wood. The mother branches or limbs should not be numerous, but well marked, equal in strength, and regularly disposed. The side branches should be pretty abundant, short, and not so vigorous as to rival the leading members. To ensure regularity, training should commence with maiden plants; leaders of equal strength should be selected, and encouraged to grow out longitudinally as much as possible, and all crowding among the inferior shoots should be prevented. In *riders* this form passes into the stellar arrangement. The French have made considerable improvements in this mode of training, some of which are noticed, *infra*, under the article Peach.

Fig. 5.

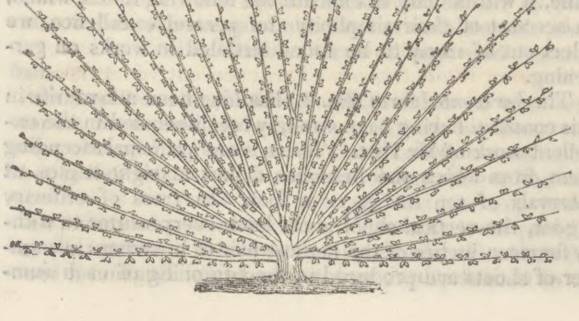


Fig. 6.

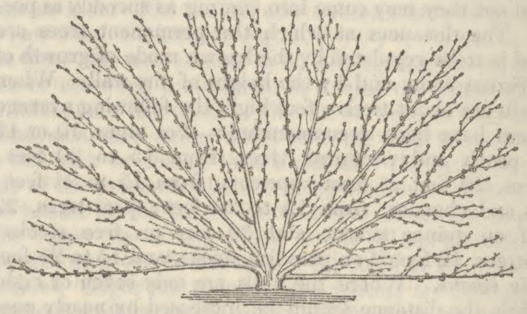
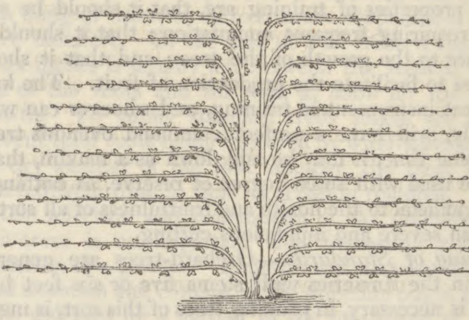


Intermediate between horizontal and fan training, is the *half-fan*, described in the first volume of the *Caledonian Horticultural Society's Memoirs*, by Mr Smith, gardener at Hopetoun-House, and practised by him with great success. It is nearly allied to the horizontal form, but the branches form an acute angle with the stem, and are supposed thus to favour the equal distribution of the sap. In the winter pruning, three and sometimes four central branches are cut back; the shoots which arise from these are arranged in the fan order, and, as they elongate, are gradually brought into the horizontal position. The tree is finished at top as in the horizontal form. Sometimes, as in fig. 7., two vertical stems are adopted. For vigorous trees, this figure seems to combine the advantages of both the foregoing varieties.

Fig. 7.



The choice of particular modes of training is too often determined by mere fashionable prejudice, which leads to the application of the same form to all sorts of trees. Thus the French are apt to reduce every thing to the *fan* system, whilst some English horticulturists are inclined to force trees of the most rambling growth into the pillory of a *horizontal* arrangement. Such a uniformity cannot possibly be in accordance with nature. The enlightened cultivator will employ various forms, and will determine for himself which is the most appropriate, not only for every species, but even for each particular variety of fruit-tree. By attentive observation and rational experiment, more knowledge in this department may be attained in a few years, than by a whole life spent in routine practice.

As supplementary to the preceding remarks on training, we may mention some of the expedients for inducing a state of fruitfulness in trees. Of these, the most common is the cutting back of the roots to within three or four feet of the stem; an operation which is generally found efficacious, when barrenness proceeds from over-luxuriance and too copious a supply of sap. To attain the same end, recourse is sometimes had to *ringing* the branches or stem, that is, removing a narrow annular portion of the bark. The trees, it is said, are thereby not only rendered productive, but the quality of the fruit is at the same time apparently improved. The advantage is considered as depending on the obstruction given to the descent of the sap, it being thus more copiously afforded, in its elaborated state, for the supply of the buds. The ring should therefore be made in spring, and of such a width that the bark may remain separated for the season. It ought to be observed, however, that none of the stoned fruit-trees are benefited by ringing. Analogous to this practice is decortication, or the removing of the old cracked bark from the stems of apple and pear trees, a practice warmly recommended by Mr Lyon of Edinburgh, and some other cultivators, but which has never been extensively adopted. Sometimes barrenness proceeds from defect of climate and poverty of soil; in which case, a warmer situation and more generous treatment are the most effectual remedies. Fruit-trees should never, if possible, be allowed to become stunted; for in this state they produce only worthless fruit, and acquire a habit which scarcely admits of amelioration.

Protection of Blossom.—In our variable climate, and particularly in the northern and eastern parts of the island, it is very desirable that the horticulturist should be provided with the means of defending the blossom of his fruit-trees from the late frosts in spring. For this purpose, some cultivators partially cover their walls with branches of fir or beech, or the fronds of the common *braken* fern (*Pteris aquilina*), fastened firmly by several points of attachment, to prevent rubbing. Others recommend frames covered with bunting, osnaburg or similar light fabrics, set in a sloping position in front of the trees. Screens formed of reeds have been used, and nettings of worsted-yarn or of straw-ropes have been employed with good effect. Whatever contrivance serves to interrupt radiation, though it may not keep the temperature much above freezing, will be found sufficient. Standard fruit-trees must be left to their fate, and, indeed, from the lateness of their flowering, they are generally more injured by blight, and by drenching rains, which wash away the pollen of the flowers, than by the direct effects of cold.

CULTURE OF HARDY FRUITS.

We now proceed to the more special culture of the inmates of a British fruit-garden. We shall begin with the more tender, but for details regarding these, we must, to a considerable extent, refer to the forcing department, in which alone many of the finer fruits can be perfected. The nomenclature of the numerous varieties of the principal fruits is still in an uncertain and unsatisfactory state. Mr Thompson, of the Horticultural Garden at Chiswick, has, however, with much discrimination and judgment, settled the synonyms of many of those chiefly cultivated in our gardens; and we shall therefore (when the contrary is not intimated) adopt the names employed in the second edition of the London Horticultural Society's Fruit Catalogue.

The GRAPE VINE (*Vitis vinifera*) can scarcely be said to be a hardy fruit in our climate. In every case it requires a good aspect; and north of York, a crop of *dessert* grapes cannot be expected without the aid of a hot wall. In the extreme south-west districts of England, indeed, grapes fit for the manufacture of wine, perhaps equal in quality to those in the north of France, might be produced on dwarf standards; and there is abundant historical evidence that productive vineyards once existed in that part of the country.

In the Lond. Hort. Soc. Catalogue, 182 varieties of grapes are enumerated. Some of these, however, have not as yet been well ascertained; some are pronounced indifferent, and others worthless. We shall name only a few of those most deserving the attention of the cultivator.

Miller's Burgundy. This sort is distinguished by the hoary pubescence of its leaves. It is a black grape, with short compact clusters, small round berries, and clear, high-flavoured juice. It is hardy, ripening completely on a south wall.

Black Damascus. Bunches large, with round berries and sweet juice. This valuable late variety does not set well, and the bunches are improved by the blossom being dusted with the pollen of some hardy kind.

Frankenthal. A valuable grape, resembling the black Hamburgh. Bunches moderate in size, berries obovate, flavour excellent. Succeeds best in a warm vinery.

Frontignan (or *Frontignac*). Five varieties under this appellation, and distinguished by the names of *black, blue, grizzly, red, white,* are mentioned in horticultural catalogues. They vary in colour and form of the cluster. The berries are round, the skin thick, and the juice of a rich muscat flavour. They are all of the highest excellence.

Black Gibraltar, or *Red Hamburgh* of Lindley. This is an excellent grape, with large clusters, and large dark-red berries, full of a sweet juice.

Black Hamburgh. This is a well-known grape, of great value, and perhaps more generally cultivated for the dessert in this country than any other sort. It ought to be in every collection.

Black Lombardy (or *West's St Peter's*). Bunches large, berries round, skin thin, with a sweet flavour; an excellent late sort. The fruit will hang on the vines till March.

Royal Muscadine, L. Hort. Cat. or *White Muscadine* of Lindley. Usual Chasselas of Paris. This, though not a first-rate grape, is a favourite with many. Bunches large, berries white, round, with sweet flavour.

Muscat of Alexandria. Bunches long, berries white and oval, with a delicious muscat flavour. This most admirable variety requires a high temperature, and should properly have a small vinery for itself.

Pitmaston White Cluster. This excellent variety sprang from a seed of the small black cluster grape. The bunch is compact, the berry is round, when ripe of an amber colour, bronzed with russet on one side. It comes to perfection on the open wall in England, and is also well suited for forcing.

White Sweet Water. Bunch loose, berries round, flavour sweet. It ripens early, generally from the middle to the end of September; and in the south of England it suc-

Fruit Garden.

ceeds against the open wall. The bunches should be allowed to hang until they be perfectly ripe, when the berries acquire a slight russet colour. It has long been a favourite grape.

Stillward's Sweet-Water is a recent variety, of equal merit.

Black Morillon, or *Burgundy Grape*, or *Small black cluster*, ripens in England against a south wall.

The *Black Prince* is of easy cultivation in a common vinery, and the berries are of a pleasant flavour.

The *Zante*, or *Corinth Grape*, is often called Zante Currant. In general it is a shy-bearer, and the berries are small; but Mr Gow, gardener at Tulliallan, having fertilized some bunches with the pollen of the Black Hamburgh, found that they set more freely, and that the berries were larger and better flavoured; a hint worth attending to in other cases.

Verdelho. Bunches loose, colour greenish-yellow, berries small, oval, numerous; when fully ripe, of a rich saccharine flavour. It is the principal grape cultivated in Madeira for making the celebrated Madeira wine. The plant grows vigorously; and Mr Knight has observed of it, that the same degree of shade which would render the greater number of sorts wholly unproductive, scarcely affects the fertility of this; a convenient property, which adapts it for the back wall of a glazed house. The same horticulturist mentions another economical property of the verdelho: it bears plentifully when planted in very small pots: a few pots of it may therefore be introduced among green-house plants in early spring; the almost leafless stems do no injury till the end of May, when some of the more hardy ornamental plants can be set abroad; and during the warm months which follow, when the green-house is otherwise empty, abundant crops of these grapes may be procured.

Esperione, or *Turner's Early Black.* The bunches are large and shouldered, not unlike those of the Black Hamburgh. The berries are of a fine dark colour, with a bluish farina: the pulp adheres to the skin; and though neither highly flavoured nor melting, it is very pleasant. This grape ripens on the open wall near London.

The *Syrian Grape* is remarkable for the extraordinary size and beauty of its bunches; but it is a late variety, and the berries have not much flavour. This is generally regarded as the kind produced in the valley of Eshcol, a cluster of which was brought to the camp of Israel swung on a staff between two of the spies; not probably on account of its weight, but (as Dr Clarke observes) to prevent the berries from being bruised.

In addition to the above, the editor of the *Lond. Hort. Cat.* mentions the following as excellent grapes:—Ciotat, or Parsley-Leaved; Genuine Tokay, or White Morillon; Chasselas Musqué; Chasselas précoce; Elford; Lunel; Mignonne White Cluster; Black Morocco; Black Muscadine; Petersburgh; Raisin des Carmes; White Tokay, and Black Tripoli.

The kinds commonly grown on the open wall in England are the Miller Burgundy, Esperione, White Muscadine, and White Sweet-Water. In the north of England, and in the south of Scotland, vines always require hot walls. At Erskine-house, on the Clyde, Black Hamburgh grapes are every year produced against a hot-wall, equal in size and flavour to those of the vinery or hot-house. In some gardens, an entire wall is dedicated to vines, but, in general, they occupy only the interstices between other trees. Mr Williams of Pitmaston trained a vine under the coping of a wall to the extent of fifty feet, and bent down the shoots at intervals to fill up the spaces between the fruit-trees, and he found that the grapes were the finer the farther they were distant from the stem. The culture of grapes on a wall does not differ materially from that practised in a moderately worked vinery; we shall therefore defer any further observations, till we resume the subject in treating of the forcing department.

The Fig-Tree (Ficus Carica) is not a great favourite in this country, the fresh fruit not being much relished, and our tables being supplied with a vast abundance of dried figs imported from the Mediterranean. Every good garden ought, however, to contain a few trees, to furnish an occasional dish; and we doubt not that the fresh fruit, if it were more common, and better grown, would be more liked. The foliage of the tree is large and elegant; and the mode of fructification is curious: the pulpy part, which we call the fruit, being, in fact, a common receptacle, and the anthers and stigmata being produced inside. The nomenclature of figs is still very uncertain, and it is with some hesitation that we give the following names:—

1. Black Ischia.
2. Black Genoa.
3. Large Blue, or purple.
4. Brunswick or Madonna.
5. Brown Ischia or Miller's chestnut fig.
6. Murrey-coloured or Brown Naples.
7. Pregussata.
8. Lee's Perpetual.
9. Early White.
10. Marseilles or Figue blanche.

Of these the Marseilles, the Early White and Black Ischia, and Large Blue, are best adapted for forcing; the others are suitable for walls. Lee's perpetual answers well for either mode of culture; but it is not mentioned by Loudon or by Lindley, being probably regarded by them as a sub-variety of the Large Blue.

Fig-trees may be propagated by cuttings put into flower-pots, and placed in a gentle hot-bed. They are, however, most speedily obtained from layers. The shoots laid down should be two or three years old; and these, when rooted, will form plants ready to bear fruit the first or second year after planting. Suckers ought never to be used.

In some places in England fig-trees are planted out as standards; and in Kent and Sussex, a few small fig orchards exist. In Scotland a south wall is indispensable, trained to which, in good situations, and when the trees are old enough, they bear remarkably well. The best soil for a fig border, is a rich friable loam, on a subsoil not retentive of moisture, or which has been effectually drained. It is advantageous to have a lofty wall, and the trees should be planted at considerable distances, perhaps not nearer than forty feet, to allow them full space to exhaust their luxuriance.

It is of the nature of the fig-tree to produce two sets of shoots, and two crops of fruit, in the season. The first shoots generally shew young figs in July and August, but those in our climate very seldom ripen. The late or midsummer shoots likewise put forth fruit-buds, which, however, do not develope themselves till the following spring, and then form the only crop of figs on which we can depend in this country.

Various modes of training fig-trees have been proposed. Mr Lindley recommends the horizontal form. Mr Knight carries up a central stem perpendicularly to the top of the wall, and then radiates the side-branches horizontally and pendently, in close contact with the wall. Luxuriance of growth is supposed thus to be checked, and the branches thrown into a bearing habit. The finest fig-trees which we have seen in Scotland, are trained in the old fan form. The shoots are laid in, thinly, at full length, and encouraged to extend themselves as fast as possible, precaution, however, being taken to leave no part of the tree bare of young wood. Much of the pruning is performed in summer by pinching off unnecessary shoots, and the knife is seldom employed, except in removing naked branches, or in cutting back to procure a supply of young wood. Some cultivators break off the points of the spring shoots, in order to produce laterals, but this must be done at an early period, not later perhaps than mid-summer, otherwise the young shoots will not ripen. The Rev. G. Swayne recommends rubbing off all the young figs which appear in autumn on shoots of the same year; observing, that for every young fig thus displaced, the rudiments of one, or perhaps two others, are formed before winter, and developed in the following year.

The winter dressing of the fig-tree takes place immediately after the fall of the leaf. The immature figs which may remain are removed, irregularities are corrected, and the shoots nailed neatly to the wall. Various modes of protecting the branches during winter have been adopted. As Argenteuil, where figs are cultivated on standards for the Paris market, the lower branches are bent downwards, and buried about six inches deep in the soil; while the upper branches are tied together, and bound round with straw and litter. Mr Swayne mentions that he wraps up the young shoots with waste paper. Mr Forsyth recommends covering wall fig-trees with the spray of laurel or yew, and then tucking in short grass or moss (*hypnum*) among the spray. Mr Smith, first at Ormiston Hall, and afterwards at Hopetoun-house, has found (*Cal. Hort. Soc. Mem.* vol. ii.) a covering of spruce-fir branches to be very effectual. The branches are so placed as to overlap each other, and to form a layer nearly equally thick on every part of the tree. The foliage of the spruce branches remains green till March, and as the light and heat increase, the dried leaves gradually fall off, and admit air and sun to the fig-branches below.

Mr Monck (*Lond. Hort. Trans.* vol. v.) states, that the same fig-tree seldom produces fruit containing both perfect stamens and pistils, and conjectures that this is the cause of the fruit being so often prematurely shed. *Caprification*, or assisting the fructifying and maturation of figs, has often been sneered at; but here we see reason in that kind of it which consisted in hanging or shaking the branches of the wild fig (*caprificus*) over the cultivated tree at the time when both were in blossom.

The Peach (*Amygdalus Persica*) is a stone-fruit of oriental origin, said to have been brought from Persia by the Romans, about the beginning of the empire; but the precise period of its introduction into our gardens, of which it has long been the pride and ornament, is not well ascertained. There are two principal varieties: the Peach, properly so called, with a downy skin; and the Nectarine, with a smooth skin. These, following the authority of Linnæus, we consider as one species; and as their culture is precisely the same, we shall speak of them as distinct only when referring to their sub-varieties. Each of these varieties is again divided by gardeners into *freestones* or *pêches*, and *clingstones* or *pavies*, according as the stone parts freely from the pulp, or adheres to it. We shall here treat chiefly of the freestones, as being most hardy, and fittest for the open wall in Britain.

Mr George Lindley, whose arrangement is the best that has hitherto been published, enumerates 60 kinds of peaches, and 28 of nectarines. In the Horticultural Catalogue, the names of 183 peaches, and of 65 nectarines, are recorded. We doubt not but that in America, where the trees are commonly raised from kernels, and grown as standards, several thousand varieties and sub-varieties might be collected. To enumerate even the limited number existing in Britain, would far exceed our limits: we shall therefore notice only a few of those which are most distinct, and best adapted to our climate.

Peaches.

Red Nutmeg, or *Avant rouge*. This is one of the earliest peaches, ripening about the beginning of August. The fruit small; colour pale yellow towards the wall, bright vermilion next the sun; pulp white, but red at the core; the juice rich and musky. The tree is an abundant bearer.

Acton Scot. This was raised by Mr Knight between the noblesse and the nutmeg peach, in 1814. The fruit is red next the sun, and white on the other side; the pulp rich, juicy, and saccharine; the tree is a good bearer, and not apt to be affected with mildew. It ripens in August.

Spring-Grove. This is another of Mr Knight's peaches, raised from the grosse mignonne crossed with the pollen of the nutmeg. It is dark red on one side, and bright yellow on the other; pulp firm, but melting, and of excellent flavour. The tree is a good bearer, but succeeds best on an apricot stock. The fruit ripens in the beginning of September.

Grosse Mignonne, L. Hort. Cat., or *Neil's Early Purple.* Fruit large; skin pale yellow, and deep purple next the sun; flesh melting; juice plentiful, and of delicious flavour. This excellent peach is a good bearer, and forces well, but the fruit does not bear carriage. It ripens in the end of August and beginning of September.

Madeleine de Courson; Red Magdalene of Miller. Blossoms large; fruit rather below the middle size; colour yellowish white next the wall, beautiful red next the sun; flesh white, with very little red at the stone; juice rich and vinous. Tree a good bearer; fruit ripening about the beginning of September. "An excellent peach," says Mr Lindley, "and ought to be found in every collection."

Royal George. This is a well-known peach, much cultivated. By nurserymen it is often given out as the Red Magdalene; but it is at once distinguished from the Red Magdalene of Miller, by the blossoms being small. Against a good wall it ripens in the beginning of September, even in indifferent seasons. Fruit large, purplish red next the sun, whitish where shaded; flesh white, varied with red next the stone which is free; melting, rich, with an abundant sugary juice. It is also one of the best kinds for a peach-house, fruiting freely, and ripening well. The foliage is, however, rather subject to mildew.

Noblesse. This has long and deservedly been a favourite in our gardens. It is a very large fruit; the skin pale red when ripe, the flesh juicy and rich. The tree is a good bearer, and the fruit ripens in September.

Bellegarde; the *Galande* of the nurseries. Fruit large and globular; skin deep red, with purple streaks on the sunny side; flesh pale yellow, very melting; juice rich. An excellent peach; the tree forces well, and the fruit ripens on the open wall about the middle of September.

Late Admirable, or *La Royale*. Fruit large; skin pale green next the wall, pale red on the sunny side; flesh greenish white, red at the stone; juice abundant, and, when well ripened, of a high flavour. "One of the very best late peaches," says Mr Thompson, "and ought to be in every collection: it is very proper for the peach-house, to succeed the earlier sorts."

Nearly allied to the preceding is the *Teton de Venus*, a beautiful fruit, but requiring a warm situation. In a good season, it ripens at the end of September; is saccharine, and at same time of fine flavour.

George the Fourth. L. Hort. Cat. 65. American Orchardist, p. 223. This is a fine large peach, of American origin; bears forcing well, and is a semi-clingstone. It is too tender for the open wall in this country.

Among other excellent peaches may be mentioned:—*Freestones*, Barrington, Chancellor, Knight's Early, Downton Early, Malta, Morrisania Pound, Royal Charlotte, Royal George Mignonne, William's Early Purple; *Clingstones*, Catharine, Heath, and Old Newington.

Nectarines.

Fairchild's Early. A beautiful little freestone, chiefly,

Fruit Garden.

however, cultivated for its earliness. It ripens about the middle of August.

Elruge, L. Hort. Cat., 21. *Lind.* p. 287 (not of Miller). It is an excellent fruit, of a moderate size; flesh white almost to the stone, which is free. The tree forces well, and is a good bearer. Fruit ripens about the beginning of September.

Hunt's Tawny. Size moderate; skin pale orange next the wall, russet-red towards the sun; flesh deep orange, juicy and well flavoured; a freestone. A very distinct sort, worthy of cultivation for its earliness.

Early Newington. A fine large clingstone; pale green on the shaded side, bright red next the sun; juice saccharine and well flavoured. Ripens in August.

Red Roman. An excellent old clingstone, now seldom to be met with genuine, but worthy of re-introduction.

A few other first-rate nectarines may be enumerated:—*Freestones*, Brinion, Downton, Murrey (*i. e.* murrey-coloured), Pitmaston Orange, Violette Grosse, Violette Hâtive; *Clingstones*, Imperatrice, Newington Late Tawny. A very good nectarine was raised by the late Mr Henderson at Woodhall, in Scotland. It approaches the Elruge. The fruit is early, and of excellent flavour, and the tree bears plentifully. It has been named the *Woodhall nectarine.*

For information respecting the best modes of raising new varieties of peaches and nectarines, the reader may be referred to Mr Knight's papers in the first volume of the Transactions of the Horticultural Society of London. That ardent horticulturist entertains the hope, that, by repeated sowings, the peach may acquire so robust a habit as to be capable of succeeding as a standard in favourable situations in England and Ireland. But with this desirable object in view, we would rather see the number of the kinds diminished than increased; and it would be well for the country, were all the indifferent sorts banished from the nursery catalogues.

To perpetuate and multiply valuable varieties, peaches and nectarines are budded upon plum or almond stocks. For dry situations, almond stocks are preferable; and for damp or clayey loams, it is better to use plums. The peach border should be composed of a light mellow loam, such as is suitable for the vine and the fig. It should be quite free from all stagnant water, or latent dampness. It need not be of great depth, as the peach tree thrives best, and is most productive, when the roots are near the surface of the ground. In this country, nothing is a greater obstacle to success in peach culture than trenching the borders, and cropping them with vegetables. We believe that, in many instances, all that is required to remedy sickly and unfruitful trees is to bring up their roots within five or six inches of the surface.

The fruit of the peach is produced on the twiggy shoots of the preceding year. If these be too luxuriant, they produce nothing but leaves; and if too weak, they are incapable of maturing the fruit. To produce these, then, in sufficient abundance, and of requisite strength, is the great object of peach training and pruning. All twiggy trees naturally fall into the fan form; and accordingly this has generally been adopted in the culture of peaches. Some have followed the horizontal arrangement, and Mr Knight has recommended a method, the principal purpose of which seems to be to thwart the usual mode of growth of the tree. In reference to such arrangements we can only say:

> Naturam expelles *furca*, tamen usque recurret.

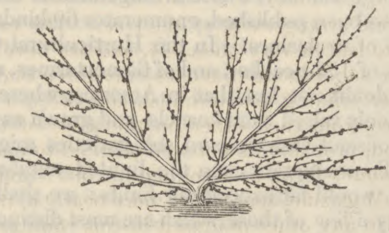
We shall first notice the old English method, and then briefly the French, and other new varieties of training.

The *old an* form is very nearly that which we have already given (*supra*, p. 638,) as a specimen of fan training for twiggy trees. The young tree is often procured when it has been trained for two or three years in the nursery, but it is generally better to commence with a *maiden* plant, that is, in the first year after it has been budded. It is then headed down to five or six buds, and in the following summer two or four shoots, according to the vigour of the plant, are trained in; the laterals also being thinned out, and properly nailed to the wall. Suppose there are four branches, in the following winter the two central ones are shortened back to produce others, and the inferior ones are laid in nearly at full length. In the following season additional shoots are sent forth; and the process is repeated till eight or ten principal limbs or *mother branches* be obtained, forming, as it were, the frame-work of the future tree. These mother branches are occasionally raised or depressed, so as to maintain their equilibrium, and are as much encouraged to grow outwards as is consistent with the regular filling up of the tree. The laterals are carefully thinned out (by pinching off with the fingers) in summer; and the remainder are nailed in, to afford subordinate members and bearing wood. When the centre of the tree has been filled up, all the training necessary is merely to prevent the inferior members from acquiring an undue ascendency over the mother branches. It is highly advantageous to have abundant space, and to draw the tree outwards, so that it be thin, but nowhere destitute of young shoots.

Meanwhile the pruning for fruit has been going on. This consists in shortening down the laterals which had been nailed in at the disbudding, or summer pruning. Their length will depend on their individual vigour, and the luxuriance of the tree. The buds, which are generally double, or rather two together, with a fruit bud between them, seldom occur quite close to the insertion of the shoot. Perhaps two or three pairs are left with a wood-bud at the point to afford a growing shoot, in order to act as its lungs, for it is necessary that there should be leaves above the fruit. When the fruit begins to swell, the point of this leading shoot is pinched off, that it may not drain off the sap. Any young shoot from the wood-eyes at the base of the bearing branch is carefully preserved, and in the following winter it takes the place of the branch which has borne fruit and is cut out. If there be no young shoot below, and the bearing branch be short, the shoots at the point of the latter are pruned for fruit; but this must be done cautiously; and if the bearing branch be long, it is better to cut it back for young wood. It is the neglect of this which constitutes the principal error of the English fan system as it is usually practised. Several times during summer the trees are regularly examined; the young shoots are respectively topped and thinned out; those that remain are nailed to the wall, or braced in with pieces of peeled willow, and the whole trees are occasionally washed with the force-pump.

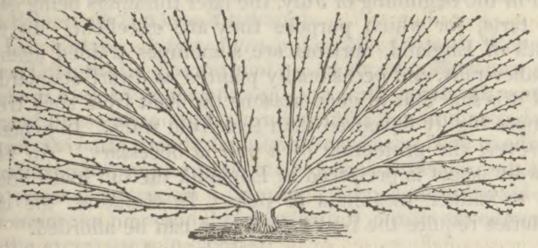
The *Montrueil form* is described at length in the Horticultural Tour, p. 429, or in the *Cal. Hort. Mem.* vol. iv. p. 145. The principal feature constitutes the great principle of all French training, the suppression of the direct channel of the sap. Four, more commonly two, *mère branches* are so laid to the wall that the central angle contains about 90°. The other branches are all treated as subordinate members.

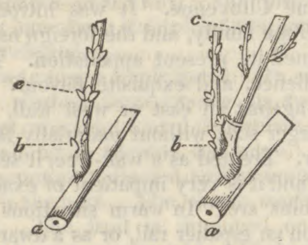
Fig. 8.



The form *à la Dumoutier* (so called from its inventor, and described at great length by Lelieur), is merely a refinement on the Montrueil method. It will be sufficient to mention to the experienced trainer (and none other can be expected to execute this form), that the formation of the tree commences with the inferior limbs, and proceeds towards the centre, the branches being lowered from time time, as the tree acquires strength. What is most worthy of notice in this method, is the management of the subordinates in the pruning for fruit. When a shoot promises blossom, it is generally at some distance from the point of insertion into the old wood, and the intermediate space is covered with wood buds. All the latter, therefore, which are between the old wood *a* and the blossom *c*, in the outer figure, except the lowest *b*, are carefully removed by *ebourgeonnement.* This never fails to produce a shoot, *b* in the inner figure, the growth of which is favoured by destroying the useless spray above the blossoms, and pinching off the points of those which are necessary to perfect the fruit. A replacing shoot is thus obtained, to which the whole is invariably shortened at the end of the year. The branch thus treated is called the *branche de reserve.*

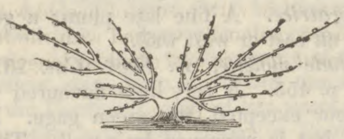
Fig. 9.





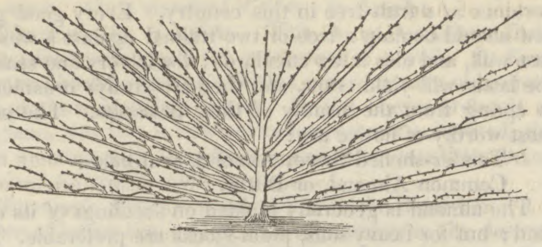
The form *à la Sieulle* is another modification of the Montrueil training, for an account of which we must again refer to the Horticultural Tour. Fig. 10. will give an idea of the general arrangement of the tree. The two mother branches are laid in very obliquely, and are never shortened. On the subordinate branches only three buds are left, at the winter pruning, one terminal, and two at a considerable distance from each other on the sides of the shoot. This method, probably, is not well adapted to our climate.

Fig. 10.



Mr Seymour's form, as described in vols. i. and ii. of the Gardener's Magazine, approaches more nearly to the French methods than any other practised in this country. It will be seen, however, from the annexed figure (fig. 11), that he does not suppress the direct channel of the sap. This circumstance, although considerable stress seems to be laid upon it, is not essential to the plan, nor is perhaps the best part of it. The principal novelty is, that the bearing shoots are all on the upper sides of the mother branches, and that these bearing shoots are wholly reproduced once a-year. The one side of this figure represents the tree *after* the winter pruning, the other side before it has undergone that operation. It will be observed, that on this last side there are pairs of shoots on the upper parts of the mother branches. The lower shoot, that, namely, which has borne fruit, is cut out, and the other is brought down into its place. This replacing shoot is shortened to about eight or nine inches, care being taken to cut at a wood-bud; and at the time of disbudding, the best situate buds, and those nearest the base, are left for the future year's bearing. To this plan it is objected, by a writer in the Horticultural Register, that the annual excision of the bearing shoots produces a series of rugged and increasingly ugly protuberances at their base and along the upper surface of the principal members; an objection which also militates against Dumoutier's form. Mr Loudon, on the other hand, declares that Mr Seymour's mode is the most perfect in theory that has been described. For ourselves, we are inclined to prefer the old fan form, when well executed, as nearest the natural habit of the tree, and as best adapted to our uncertain climate. In the training of peaches, "whatever is best administered is best;" and there is no doubt that many ingenious gardeners have only partial success, because, from the multiplicity of their engagements, their trees can receive only partial attention.

Fig. 11.



For cold and late situations, Mr Knight has recommended the encouraging of spurs on the young wood; such spurs, when close to the wall, generating the best organized and most vigorous blossoms, and ensuring a crop of fruit. They may be produced, by taking care, during the summer-pruning, or disbudding, to preserve a number of the little shoots emitted by the yearly wood, only pinching off the minute succulent points. On the spurs thus procured, numerous blossom-buds form early in the following season.

Peach-trees, particularly in the north of England, and also in Scotland, require protection from atmospherical influences, especially at the period of blossoming. As already noticed, branches of spruce or silver fir, or other spray, are sometimes woven into frames, which are fixed in front of the trees, and removed during the day in fine weather (*Cal. Hort. Mem.* i. 276). Canvass or bunting screens are equally effectual, and perhaps more easily moveable. Straw-ropes, straw-nets, and a variety of other expedients, have been proposed, and may be used according to circumstances. If the screens be applied early in the season, great benefit may be derived from retarding the blossom till the frosty nights of spring be past. If the night frost have been severe, a copious sprinkling of water over the whole tree, before the influence of the morning sun be felt, has been found by Harrison to be very useful in gradually raising the temperature of the foliage and blossoms, and thus preventing injury from the sudden transition. To trees trained against hot-walls, if fire be used in spring, screens are indispensable; but perhaps hot-walls are most beneficially employed in ripening off the fruit of the late sorts of peaches in autumn; and, what is equally important, ripening the young wood of such sorts.

The Almond-Tree (*Amygdalus communis*), a native of China, may be noticed here rather on account of its affinity to the peach and apricot, than because of its importance as a fruit-tree in this country. Every good garden should contain a tree or two trained against a west or east wall, and also a few standards; for in very fine seasons the latter will yield crops, and they are always ornamental in spring from the beauty of their blossoms. The sorts most worthy of notice are:

Tender-shelled Sweet Almond, or Jordan.
Common Almond, or Bitter.

The almond is generally budded on seedlings of its own kind; but for heavy soils, plum-stocks are preferable. The training and pruning of almond-trees on walls are much the same as in the peach or the apricot.

The Apricot (*Prunus Armeniaca*) is a native of the Caucasus and China; it was cultivated by the Romans, and was introduced into England from Italy in the reign of Henry VIII. It has always, and deservedly, been a favourite fruit. The principal varieties are:

Red Masculine. Flowers small; fruit small, roundish, yellow, and red; flesh sweet and juicy; stone impervious; kernel bitter. This is a very early sort. The tree is tender, and requires a good aspect.

Breda. Flowers large; fruit roundish, sometimes almost four-cornered, orange-coloured; juice rich; stone small, impervious; kernel sweet. The true Breda is an apricot of first-rate excellence, and in the south of England the tree bears well as a standard.

Roman. Flowers large; fruit oblong, compressed, pale yellow; flesh soft; stone impervious; kernel very bitter. The tree is a good bearer, but the fruit is fit only for preserving. It is sometimes called the Brussels,—a name also occasionally given to the preceding.

Moorpark. Flowers large; fruit roundish, compressed, orange and red; flesh parting from the stone, juicy and rich; stone pervious; kernel bitter. This is generally considered the best apricot in this country: there are several sub-varieties known under different names, and it scarcely differs from the *Abricot Pêche* of the French.

Turkey. Flowers large; fruit middle-sized, spherical, deep yellow; flesh juicy and rich, parting from the stone, which is impervious; kernel sweet. This is an excellent late variety.

Besides these, we may mention the Large Early, the White Masculine, Hemskirke, Musch-musch, and Royal. The last is a French variety of recent origin; it is excellent, and ripens earlier than the Moorpark.

Apricots are propagated by budding on muscle or common plum-stocks. Mr Knight recommends the wilding apricot as a stock for the Moorpark variety. Some gardeners have adopted the horizontal form of training, but the most usual, and certainly the best, is the common fan-arrangement. The fruit is produced on shoots of the preceding year, and on small close spurs formed on the two-year old wood. The apricot is a tree of much stronger growth than the peach, and therefore requires more room; this and the peculiarity of the spurs being kept in mind, the observations made on the training and pruning of the peach may be readily applied to this tree. It requires a summer and winter pruning. The former should begin early in June, at which period all irregular fore-right and useless shoots are pinched off; and, shortly afterwards, those which remain are fastened to the wall to become bearers. At the winter pruning, all worn-out branches, and such as are not duly furnished with spurs and fruit-buds, are removed. The young bearers are moderately pruned at the points, care, however, being taken to leave a terminal shoot to each branch. The most common error in the pruning of apricots, is laying in the bearing shoots too thickly.

The blossom comes early in spring, but is more hardy than that of the peach; the same means of protection, when necessary, may be employed. The fruit often sets too numerously; and in this case it is thinned out in June and in the beginning of July, the later thinnings being used for tarts, for which purpose they are excellent. In the south of England, apricots are sometimes trained against espalier-rails, and occasionally planted as dwarf standards; and it is said that in good seasons the fruit from such trees is more highly flavoured than that from walls. In general, however, the protection of a wall is necessary. An east or west aspect is preferred in England, the full south being apt to induce mealiness of pulp. In Scotland, the late varieties require the best aspect that can be afforded.

The Plum-Tree (*Prunus domestica*) is considered by Sir J. E. Smith as a native of England. Many of the best cultivated varieties, however, have been introduced from France. The Horticultural Society's Catalogue enumerates 274 sorts, though probably all of these are not well ascertained. We shall first notice a few of the best dessert plums, and then give a list of select kitchen sorts.

The *Green Gage* is the *Reine Claude* of the French. Being a great favourite at Paris (as it is every where else), during the ferment of the Revolution, when all allusions to royalty were proscribed, it retained its popularity under the title of Prune Citoyenne. It was introduced into England by the *Gage* family, and the foreign name having been lost, it obtained its present appellation. It is a fruit of first-rate excellence, and exquisite flavour. The tree deserves a place against an east or west wall, where the fruit acquires a larger size, without materially falling off in richness of flavour. Treated as a wall-tree, it seldom bears well till it be old; and it is very impatient of exact training, as indeed most plums are. In warm situations it may be profitably grown on an espalier rail, or as a dwarf standard.

Drap d'Or. This is a small yellow plum of high flavour, ripening in the beginning of September. On a light soil the tree is a tolerable bearer; but on a heavy soil it seldom succeeds. The fruit precedes the green gage in ripening, and resembles it in quality.

Coe's Golden Drop. A fine large oval plum, excellent either for the table, or for preserving. It keeps well; and Mr Lindley informs us, that he has eaten it exceedingly good twelve months after it had been gathered. It requires the best aspect of a wall; and will scarcely answer in a bleak climate.

Precoce de Tours. An early sort; of a dark-blue colour, with a violet bloom; pulp yellow, and of a very pleasant flavour. The tree succeeds as a standard.

Blue Imperatrice. A fine late plum; a good bearer, but requiring an east or west wall.

Reine Claude violette, L. Hort. Cat. 232. *Purple Gage, Lind.* p. 455. A very high flavoured variety, resembling, colour excepted, the green gage. It succeeds on standards, but is improved by a wall. The tree is a good bearer.

Washington, L. Hort. Cat. 266.; *Amer. Orchard.* p. 268. Fruit rather large, roundish oval, pale yellow on the shaded side, and of a fine glaucous light purple on the exposed side; of excellent quality, scarcely inferior to the green gage. The tree is vigorous, and bears well against a wall, ripening about the middle of August. Being an early plum, it will, in favourable situations, succeed as a standard. It is, as the name imports, of American origin. It ought to be in every collection.

Couper's Large Red. This is described by Mr Barnet of the Experimental Garden, Edinburgh, as of large size, oval; suture deeply cleft on one side; skin of a bluish-glaucous purple on the exposed side, the other side dull red; flesh firm, adhering to the stone; ripens in the beginning of September on a south wall (in Scotland). Although

Fruit Garden.

this is only a plum of the second quality, yet the tree well merits a place, on account of its great productiveness.

The following are also first-rate plums: D'Agen, Coe's Late Red, Downton Imperatrice, Kirke's, Nectarine, Blue Perdrigon, and White Perdrigon.

The Cheston, Fotheringham, Goliath, Orleans, Wilmot's New Orleans, La Royale, Sharpe's Emperor, Morocco, and some of the Damasks, though generally regarded as only second-rate plums, deserve notice, and should always have a place in large gardens. The Early Violet is an excellent bearer, and strongly recommended by Lindley to be planted in cottage gardens. Lucomb's Nonsuch plum should not be omitted; for when well ripened, it makes an approach to the green gage in flavour.

As kitchen and preserving plums we may specify the Damson, Shropshire Damson, Imperial Diadem, Isabella, White Magnum Bonum, Red Magnum Bonum or Imperiale; the Caledonia or Nectarine Plum, a large and handsome fruit; the Mirabelle, St Catherine, Wine Sour, and Bullace.

The finer dessert plums are propagated chiefly by budding on Muscle or St Julian stocks. They are sometimes grafted, but gum is apt to break out at the place of junction. The damson, wine sour, and other varieties, planted as standards, are generally increased by suckers, which the old plants afford plentifully. For placing against walls, trees which have been trained for two years in the nursery are to be preferred.

Plum-trees require ample space. On common walls they should be allowed from twenty to twenty-five feet of breadth over which to extend themselves. The horizontal mode of training is adopted by many. The fan form is also very commonly followed, and undoubtedly where there is room, it is the best. The shoots ought to be laid in at full length. The fruit is produced on small spurs, on branches at least two years old. The same spurs continue fruitful for several years.

Standard plum-trees require only to have a portion of their wood thinned out occasionally while they are young. The hardy kinds grown in this way are very productive, and in some places in the North of England, their produce forms a considerable article of food for several weeks, and also an article of commerce, particularly the wine sour, which is in great request for preserves. It is matter of regret that this branch of fruit culture has not, as yet, met with due attention in Scotland.

The Cherry-Tree (*Prunus Cerasus*), is said to have been introduced into Europe from Pontus, by the celebrated Lucullus, A. C. 73. From the "London cries" of Lydgate, it appears that "cherries in the ryse," or in twigs, were hawked in London at the beginning of the 15th century. Excellent sorts have at various times been introduced from the Continent, and, of late years, several first-rate new varieties have been raised in England. Geans included, the Horticultural Society's Catalogue enumerates no fewer than 219 varieties; the following may be accounted some of the best.

The *Early Purple Griotte* may be first mentioned, as being the earliest of all cherries, generally ripening in the end of May. It was introduced from Geneva a few years ago, and is not yet generally known in this country.

The *May-Duke* is one of the most common, and, at the same time, one of the most valuable cherries. In fine seasons, and on a good aspect of wall, it begins to colour in May; and in such situations it is generally ripe from the middle to the end of June. The tree also bears well as a dwarf standard, but against a wall the fruit gets larger, and does not fall off in flavour.

The *Late Duke* is a rich sweet cherry, with most of the qualities of a May-Duke. It has a very close affinity to the variety called the Arch-Duke, if it be not absolutely the same. On a standard it ripens in August.

Bigarreau or *Graffion*. This is an excellent fruit, especially when it gets the protection of a wall. In Kensington Gardens are trees of this sort a century old, which still produce abundant crops. In the cherry orchards of England, this sort is now pretty extensively cultivated, the fruit meeting with a ready sale, and vast quantities being required for the London market.

Harrison's Heart is nearly allied to the Bigarreau; it is rather of larger size and of fine appearance in the dessert, but inferior in flavour. The fruit has this advantage, that it is not liable to crack in wet weather.

Belle de Choisy, an excellent cherry. The fruit come in pairs, red, mottled with amber colour, tender and sweet. The tree bears well as a standard.

Black Tartarian, or Ronalds's Black Heart, *L. Hort. Cat.* 198; *Lind. p.* 149. Fruit large, obtuse heart-shaped; flesh half tender. "The quality is good, and in appearance it is one of the finest." It is a good bearer, and well adapted for forcing.

Waterloo. Raised by a daughter of Mr Knight, from the Bigarreau and May-Duke. Fruit black, large, obtuse heart-shaped, pulp tender. It ripens in July, and the tree is a free bearer.

Elton. Raised by Mr Knight from the Bigarreau and White Heart. Fruit large, heart-shaped, pale red, with a sweet delicious juice. The tree is a good bearer and hardy; the fruit ripens shortly after the May-Duke.

Kentish Cherry. One of the oldest and most prevalent cherries in England, abounding in the orchards of Kent. When ripe, it is of a full red colour, and its subacid flavour is very agreeable. It is commonly grown on standards, and ripens in the end of July. The *Hort. Cat.* distinguishes this from the *Flemish* or short-stalked, also a good cherry, to which it is certainly closely allied.

The *Morello*. This is a well-known late cherry, much in request for confectionery. The tree is a copious bearer, and on a south wall the fruit acquires a peculiarly rich subacid flavour. It succeeds perfectly well on a north aspect, where its fruit may be retarded to the end of October.

The *Amber*, or yellow Spanish, is a late fruit, and useful in prolonging the cherry season till the beginning of September. It requires a west wall.

Among other excellent varieties may be mentioned the Black Eagle, Black Heart, Bowyer's Early Heart, Carnation, Downton, Florence, Knight's Early Black, and the White Heart.

What are called *geans* or *guignes*, are cherries less removed from their natural state. They are usually grown as standards, and bear abundantly, particularly when old. The principal sorts are the Amber gean, a plentiful bearer, with sweet tender fruit; and the Lundie gean, a small black cherry of high flavour, which originated at the ancient seat of the Erskines in Forfarshire, but is also sometimes called the Polton gean, from a place near Lasswade in Mid-Lothian.

It may be noticed that, in the Jardin des Plantes at Paris, the black-fruited cherry-tree, or *Guignier*, is considered as a variety of Prunus Cerasus. The forest cherry-tree, P. avium, is named *Merisier;* and, besides varieties with red and with black fruit, there is a marked variety called *Bigarotier*.

The great quantities of pale-coloured cherries yearly sold in the London market are chiefly of the kinds called White Heart and Bigarreau. The dark coloured cherries are chiefly the Courone, which is often passed upon buyers for the Black Heart.

The stock preferred for cherries is the wild gean. Mr Lindley recommends that dwarf cherry-trees should be grafted, and two or three year-old stocks will do for them.

Fruit Garden.

For standard trees the stocks should be at least four years old, and they should be budded or grafted five or six feet from the ground. High stemmed cherry-trees, or *riders*, are often temporarily employed to fill up the vacant spaces on newly planted south walls, till the dwarf trees make sufficient progress; for these, stocks six or seven feet high are required.

Cherries are generally produced on small spurs which appear on the wood of the second year, and these spurs continue productive for an indefinite period. Any form of training may therefore be adopted; but, as the fruit is always finest on young spurs, perhaps fan-training, which admits of the frequent renovation of the bearing branches, is the most advantageous. A succession of young shoots should be laid in every year. For the Morello, which is of twiggy growth, and bears on the young wood, the fan form is absolutely necessary. Whatever method be adopted for general practice, care should be taken not to crowd the branches: nothing is more injurious to the productiveness of the trees than crowding of branches.

The Pear Tree (*Pyrus communis*) is considered by botanists as a native of England. Many cultivated varieties seem to have been introduced by the monks; remains of perry orchards attached to monasteries of the 14th and 15th centuries being not uncommon even in Scotland; and very ancient trees of the finer dessert pears, such as the Colmar and Longueville, occasionally occurring.

The list of cultivated pears amounts to more than 600 names; but the number of those truly desirable is not large. We shall specify some of the best dessert fruit, following the usual division of Early and Late; the former class being in season in the months of August, September and October, and the latter in November, December, and January. It is to be premised, however, that even within the limits of Britain, climate makes an important difference in the culture and ripening of pears, of which a remarkable and extreme example may be seen in the Chaumontelle,—a fruit which is produced abundantly, and ripened on standards in the west of England, and in the environs of London, while it requires a south wall near Edinburgh.

I. *Early.*

Citron des Carmes, L. Hort. Cat. 190; Madaleine, *Lind.* p. 344, in Scotland often called the Premature. This is the earliest pear; it ripens in July, acquiring a yellowish green colour; it is sweet, but without much flavour. One tree, or at most two trees, may suffice. It requires a sheltered situation.

The *Green Chisel*, called also the Hastings, and, in the market, the Green Sugar. This is not a first-rate pear: but the tree is hardy and a great bearer. It ripens in August.

The *Summer Rose*. A handsome round pear, of a russety red colour, much resembling an apple, flesh white, rich, and sugary. This is an excellent variety, succeeds on a standard, and ripens in August.

The *Jargonelle* of Britain is the *Grosse Cuisse Madame* of French horticultural writers, and the *Epargne* and *Beau-present* of French practical gardeners. This is the most common and most esteemed of our early autumn pears. Against a wall the fruit attains a large size and a beautiful appearance; but it is not of so high a flavour as from standards or espalier-rails. The fruit does not keep well, and the tree should therefore be planted in various situations to prolong its season, as it is rather difficult, when it disappears, immediately to supply its place. Beautiful dwarf trees may be formed by grafting on the common white thorn, which, however, are not very patient of transplanting. The French jargonelle is green on one side and red on the other, and is a fruit of inferior quality.

The *Ananas d'Eté* is scarcely noticed by our horticultural writers; but it seems a good variety to succeed the jargonelle. In the Experimental Garden at Edinburgh, it ripens on a standard in the second week of September. Mr Barnet describes it as of middle size, about two and a half inches broad, tapering a little towards the stalk, round at the top, eye small, slightly sunk in a cavity; red on the exposed side, green and somewhat russety on the other; flesh white, melting, with a pleasant sweet juice.

The *Summer Francréal*, or the *Yat* of Holland, may be noticed as another pear to follow the jargonelle, as it ripens about the middle of September. The tree proves, in general, a great bearer.

The *Longueville*. Some very ancient trees of this variety exist at Jedburgh: and, in the garden of the Regent Murray at Edinburgh, there are several which apparently are coeval with the times of the Regency. Though the name is now unknown in France, it is conjectured that the tree was brought over from that country by the Douglas, when Lord of Longueville, in the fifteenth century. The fruit is large, of a thick conical shape, green, and of considerable flavour. It ripens in September.

The *Green Pear of Yair*. This variety is of Scottish origin. The fruit is obovate, green, and of a middle size; flesh juicy and well-flavoured. It is sometimes placed on a wall to succeed the jargonelle; but it is always better from standards. On old trees, in light soils, it sometimes acquires a lemon colour, with a high musky flavour. Ripens in September and October.

The *Duhamel* is a good autumn pear, with a delicate flavour. It comes in immediately after the green yair, and helps to fill up a gap in the pear season, especially in Scotland.

The *Seckle*, of American origin, deserves a place; for the tree is of dwarfish size, and suited for a border standard, and it seldom fails to yield a crop. The fruit is small, but melting and well-flavoured. It does not keep.

The *White Doyenné*. This is an excellent sort, when used at its perfection. In warm situations, it is well adapted for dwarf standards. Ripens in September and October.

The *Red Doyenné*, or, as it is sometimes called, Gray Doyenné, is also an excellent autumn pear, doing best on a quince stock.

The *Elton*. Capital as a standard, and strongly recommended by Mr Knight. The tree produces healthy wood, and the fruit ripens in September and October.

The *Early Bergamot* was introduced from France in 1820. It is one of the very best early pears, as the tree bears freely on an open standard.

The *Autumn Bergamot*, or English Bergamot, has been long known as one of the most highly flavoured pears. It is not the Bergamotte d'Automne of the French, which is liable to canker in this country, while the English bergamot is not liable. In England the tree succeeds perfectly well as a standard; in Scotland it answers in good seasons, but here it is deserving of a west wall. The fruit is of a depressed globular shape, not large; the flesh juicy, sugary and rich, a little gritty next the core. It ripens towards the end of October, but does not keep.

To the list of summer and early autumn pears might be added the Musk Robine, Summer Bonchretien, and Williams's Bonchretien, requiring the protection of a wall; and the Lammas Pear of Scotland, "soon ripe, soon rotten," which succeeds perfectly well on open standards; Ambrosia, Belle et Bonne, Beurré d'Amalis, Bishop's Thumb, Caillot Rosat, and the Hazel Pear.

II. *Late.*

The *Brown Beurré* (Red and Grey Buerré of various

Fruit Garden.

authors). This is a first-rate melting pear. Against a wall with a good aspect, and with a fresh soil, the tree is an abundant bearer. Ripens in October and November.

The *Beurré de Capiaumont.* This is one of the best new Flemish varieties. The fruit is beautiful and well-flavoured. It ripens in October and November. The tree is a great bearer and hardy.

The *Moorfowl Egg.* There are two varieties, both of Scottish origin, of which the Galston Moor-fowl Egg is the best. The fruit is not attractive in appearance, but it is of admirable quality. The tree is hardy, and should be grown as a standard.

The *Gansel's Bergamot* (sometimes called Brocas' Bergamot). This noble pear, which has scarcely been rivalled, certainly not surpassed, by any of the imported varieties, is of English origin. Its blossoms are too tender to enable the tree to succeed as a standard; but it deserves a wall, and it should be placed on various aspects to prolong its season. The fruit ripens in November and December.

The *Marie Louise.* This excellent and large pear was raised by the Abbé Duquesne, and named after the Ex-Empress of France. "It is," says Mr Thompson, "one of the very finest, even as a standard, on which it bears abundantly; it succeeds also well on a north wall." In Scotland it is the better for an east or west aspect; but on a standard in a sheltered garden at Luffness, East Lothian, the fruit has attained the weight of 15 ounces. It ripens in October and November.

Beurré d'Aremberg. This most excellent pear was first brought into notice and recommended by the Caledonian Horticultural Society's deputation in 1817 (*Hort. Tour.* p. 321). It is perfectly melting and without grittiness, and rich, sweet, and high-flavoured. The tree succeeds either trained against an east or a west wall, or as a standard in any sheltered situation.

Crasanne. An old French sort, of excellent quality, with a tender and finely flavoured pulp. The tree deserves an east or west aspect on the wall, and it succeeds also on an espalier-rail. The fruit ripens in November and December.

The *Urbaniste* is a very good variety, of a large size, and ovoglobular shape; skin of yellowish colour, with small russety spots; flesh white, melting, with a sweet well-flavoured juice. In Scotland ripens against a south wall by the beginning of November.

Colmar. This is a first-rate pear, with a white flesh, and of high flavour. In Scotland the tree requires a south wall. From this the Poire d'Auch of the Continent seems scarcely to differ. It keeps till February or March.

Passe Colmar. An admirable Flemish variety lately introduced into this country; of excellent flavour; hardier, and a more abundant bearer than the preceding, and more easily ripened. It is in maturity in December and January.

Poire Neill was raised by M. Van Mons of Louvain, about the time of the visit of the Caledonian Horticultural Society's deputation to Belgium (in 1817). It is a large handsome fruit, with a very white pulp, mellow, and abounding with a saccharine and slightly musky juice. It is in season during the month of October, and should be gathered a few days before it be ripe. The tree succeeds as a standard at Edinburgh, and bears freely.

The *Easter Beurré.* Fruit large, obovate, green and brown; flesh whitish-yellow, buttery, and extremely high-flavoured. "It is," says Mr Thompson, "hardy and a good bearer; one of the most valuable spring sorts, compared with which the early pears of short duration deserve not a wall; its extensive cultivation for a long and late supply is, without hesitation, strongly recommended." In season from January to March. As the tree ripens its wood readily, it succeeds as a standard, even in Scotland, and yields fruit superior in flavour to that from the walls.

Beurré Rance. A Flemish variety raised by the late M. Hardenpont; "the best very late sort yet known," *Hort. Cat.* It ripens with difficulty in Scotland; but was found to be the best pear produced in competition at the meeting of the Caledonian Horticultural Society in the month of March 1835.

The following, respecting which our limits will not permit us to go into detail, may be considered as highly valuable sorts as late autumnal and winter pears:—Autumn Colmar, Aston-town, Echassery, Delices d'Hardenpont, Beurré Bosc, Beurré Diel, Beurré Spence, Bezi Vaet, Bezi de la Motte, Chaumontelle, Sylvange, Downton, Glout Morceau, St Germain, Duchesse d'Angoulême, Louise bonne, Hacon's Incomparable, Winter Nelis, Black Auchan, Swan Egg, Doyenné gris, Flemish Beauty, and Napoleon.

Some excellent new varieties of dessert pears have, of late years, been raised by Mr Taylor, gardener at Dunmore Park, under the directions of the noble proprietor, who is a scientific horticulturist. These have not yet been described or published; but the Dunmore Brown Beurré and Taylor's Seedling have been found to be of the first quality.

Of the *Kitchen Sorts,* or stewing pears, we may name the Bellisime d'Hiver, Catillac, Uvedale's St Germain, Warden or Black Worcester, and the Gilogil. These are placed on inferior walls, or upon espalier-rails, or kept as dwarf standards. The Uvedale's St Germain fruit often attains a large size, especially against a wall.

Pear-trees are grafted either on what are called free-stocks or on dwarfing stocks: for the former, which are intended for full-sized trees, the seeds of the wilding pear should be sown; but frequently the pips of the perry pears, and sometimes of the common cultivated sorts, are used. For dwarfing, the quince is preferred; but the white-thorn, as already mentioned, is occasionally employed. Where the space is limited, or the ground is damp, the dwarfing stocks are the more suitable. It is a favourite doctrine with some, that by budding or grafting on quince or hawthorn, pears of too melting and sugary a quality acquire firmness and acidity; to what extent this holds good has not been correctly ascertained, but that the stock exerts a certain degree of influence on the fruit is beyond dispute. Some of the finer pears do not take readily on the quince. In this case double working is resorted to. For example, the Virgouleuse may be easily budded on the quince, and the Beurré d'Aremberg will afterwards succeed freely on the Virgouleuse. It may be mentioned in passing, that the ancient horticulturists seem to have supposed that a fruit was improved by double working; and that the term *reinette,* a name applied to a class of apples, is considered as having been derived from the Latin *renata,* that is, a tree grafted upon itself.

In selecting young pear-trees, some prefer *maiden plants,* that is, plants one year grafted; but if good trees, trained for two or three years, can be procured, so much the better. It is important to ascertain that the stock and stem be clean and healthy, and to take great care that no injury be done by bruising or tearing the roots, in lifting and removing. The young trees may be planted at any time, in mild weather, from the fall of the leaf to the beginning of March. Wall-trees require from 25 to 30 feet of lineal space when on free stocks, and from 15 to 20 feet when dwarfed. Standards on free stocks in the orchard should be allowed at least 30 feet every way, while for dwarfs 15 feet may suffice. Where the trees are trained *en pyramide* or *en quenouille,* (see p. 637) they may stand within eight feet of each other. It is very desirable that the pear orchard should be in a warm situation, with a soil deep, substantial, and well drained, or free from injurious latent moisture. Without attention to these circumstances, pear-trees seldom succeed.

The fruit is produced on spurs, which appear on shoots more than one year old; the object of the pruner, therefore, ought to be to procure a fair supply of these spurs. The mode of training wall pear-trees most commonly adopted is the horizontal; but each of the forms already mentioned (p. 638), has its advantages, and is peculiarly adapted to some particular habit of growth in the several varieties. For the St Germain, and other twiggy sorts, we should prefer the fan form; for the Gansel's Bergamot, and other strong growers, the half-fan, or the horizontal. In the latter forms the trees may often be found fifteen, twenty, or even thirty years old, during which time they acquire an undue projection from the wall, and become scraggy and unmanageable. On the other hand, the finest fruit is produced on young spurs, clearly indicating the necessity of a frequent renovation of the spurs. This would lead us to prefer the fan-form, not, indeed, that which is commonly practised, and represented in fig. 5. p. 638, for in it the spurs are as immovable as in any other arrangement; but rather that recommended for peaches, in which there is a continual renewal of the branches. Or if we did adopt the horizontal form, which has certain advantages, it would be that modification exhibited in the right side of fig. 4. *a*, p. 638. This is the method followed by Harrison in treating the Jargonelle.

The summer pruning of established wall or espalier-rail trees, consists chiefly in the timely displacing or rubbing off of the superfluous shoots, retaining only those which are terminal, or well placed for lateral branches. Where spurs are wanted on the older wood, about two inches of a foreright shoot are left; and if this be done early, that is before the shoot has become ligneous, it seldom fails to form fruit-buds. In horizontal training, the winter pruning is nothing more than adjusting the leading shoots, and thinning out the spurs, which should be kept close to the wall, and allowed to retain only two, or at most three buds. In fan-training, the subordinate branches must be regulated, the spurs thinned out, and the young laterals, which were loosely nailed in, during summer, must be finally established in their places. No crowding of branches should be permitted. Where horizontal trees have fallen into disorder, they may be renovated in the manner represented by fig. 466, left side, a procedure patronized by Mr Knight: or all the branches may be cut back to within nine inches of the vertical stem and branch, and trained in afresh, as recommended by Mr Lindley.

When some of the finer pear-trees produce an abundance of blossom, but do not *set* well, as not unfrequently happens, artificial impregnation may be partially resorted to; that is, the blossom of some other kind of pear, plentifully provided with pollen, is taken, and the farina is dusted over the best looking blossoms of the unproductive tree.

Summer and autumn pears should be gathered before they be fully ripe, otherwise they will not in general keep more than a few days. The Jargonelle, as Forsyth rightly advises, should be allowed to remain on the tree, and pulled daily as wanted, the standard fruit thus succeeding the produce of the wall trees. In reference to the Crasanne, Mr Lindley recommends gathering the crop at three different times, the first a fortnight or more before it be ripe, the second a week or ten days after, and the third when fully ripe. The first gathering will come into eating latest, and thus the season of the fruit may be considerably prolonged. It is evident that the same method may be followed with the Brown Beurré, Gansel's Bergamot, and any other which continue only a short time in a mature state.

The APPLE-Tree (*Pyrus Malus*), under the name of the Crab, is a native of Britain. Most of the cultivated sorts, however, are of foreign origin, and it does not seem probable, that we possess at present any good variety which is more than two hundred years old. The finer, high-flavoured apples are prized for the dessert; the juicy and poignant sorts are in request for tarts and sauce; whilst those of a more austere nature are manufactured into cider. In the second edition of the *London Hort. Society's Catalogue*, no fewer than 1400 varieties are enumerated; many of them doubtless not well ascertained, but about 175 are pronounced to be first-rate sorts. With such a multitude before us, it would be vain to attempt detailed descriptions: we shall therefore do little more than give a classified list of those most worthy of attention, referring the reader for further information to the Catalogue itself, to Mr Lindley's *Guide to the Orchard and Kitchen Garden*, and to Mr Rogers' *Fruit Cultivator*.

Table Apples.

The earliest of these are the following:—The Juneating, or White Geniton, which begins to ripen in the end of July, and, being sugary and slightly perfumed, forms a welcome addition to the dessert. The Early Red Margaret is often cultivated; it is sometimes called Red Juneating, and in Ireland Peach Apple. The Summer Crofton, or White Crofton, is of Irish origin: the tree bears abundantly; and if the fruit be scarcely equal to the Juneatings for the dessert, it is very desirable for culinary purposes in August. The Thorle, originating in the Carse of Gowrie, is an early apple of considerable merit, although not mentioned by Mr Lindley. The Oslin or Arbroath Pippin, and the Early Julien of Clydesdale, also deserve notice. The Summer Golden Pippin, the Red Quarenden of Devonshire, and the Summer Calville, are likewise excellent early dessert apples.

To succeed these in the autumn we have many fine sorts, such as the Early Nonpareil or Hick's Fancy; the Red Ingestrie and Yellow Ingestrie, raised by Mr Knight; the Doonside, a capital Ayrshire production; Autumn Pearmain or Royal Pearmain of the London nurseries; Shepherd's Fame; Baird's Favourite; Pomme de Niege; and Bourassa; Franklin's Golden Pippin; Old Golden Pippin; King of the Pippins or Hampshire Yellow; Please Lady; Kerry Pippin, one of the finest Irish apples; and the Cole Apple or Scarlet Perfumed.

The winter dessert apples are very numerous, so that only a few can be mentioned. The Ribston Pippin has long maintained a pre-eminent character for its rich juiciness and highly aromatic flavour. If the tree be trained to a wall, the fruit is much improved in size and beauty; but Mr Rogers, in his *Fruit Cultivator*, is decidedly wrong in thinking that it is heightened in flavour; for, on the contrary, the flavour is deteriorated. The Ribston is an old variety; and there is reason to fear that, like the Grey Leadington (formerly the boast of Scottish orchards), it is verging to decay and extinction. Hubbard's Pearmain is a Norfolk apple of the very finest quality, and too little known, especially in Scotland; the tree does not grow large, is quite hardy, and an abundant bearer, either as a standard, or when trained to an espalier-rail. The Dutch Mignonne is another admirable dessert apple, too little known or attended to. The Golden Harvey, or Brandy Apple of Forsyth, is a beautiful fruit, and Mr Lindley characterizes it as rich, juicy, spicy, and high-flavoured: the tree is not a large grower, is very hardy, and a great and constant bearer; and no garden, adds Mr Lindley, "capable of containing ten trees, ought to be without one of it." The Downton Pippin, raised by Mr Knight from the orange pippin of Herefordshire, dusted with the pollen of the old golden pippin, must not be omitted. The tree is a great bearer; the fruit ripens in the end of October and keeps till January; it has a brisk, subacid juice, which becomes saccharine. The fruit should not be gathered until it

Fruit Garden.

has acquired a bright yellow colour, and part freely from the tree. To these may be added the Beachamwell Seedling; Borsdorffer; Court of Wick Pippin; Wood's Transparent; Margil; Newton Pippin; Scarlet Crofton; Golden Pearmain; Scarlet Pearmain; Gravenstein; Paradise Pippin; Old Nonparcil; Ross Nonpareil; Scarlet Nonpareil; Golden Rennet; Reinette de Canada; Sykehouse Russet; and the Sam Young, an excellent Irish apple, brought into notice by Mr Robertson of Kilkenny.

Kitchen Apples.

These are very numerous, and the names of a few of the best can only be given. We begin with the Scottish Hawthornden; though the tree is liable to canker, yet it comes early into bearing, and the fruit is excellent. The Codlins may be next named, particularly the Spring Grove, the Kentish or Fillbasket, the Keswick, the Dutch, and the Manks. Dumelow's Seedling, the Fulwood, the Green Fulwood of Mr Mathew, the Nonsuch, Minshul Crab, Hanwell Souring, Cat's-head, Alexander, Brabant Bellefleur, Blenheim Pippin, Hunt-house of Yorkshire, Norfolk Beaufin, and Forman's Crewe, are all good. Among the best long-keeping apples are the Scottish Gogar Pippin or Stone Pippin; and the Yorkshire Greening and Northern Greening, particularly the latter; Winter Strawberry Apple; Winter Lud; Cambusnethan Pippin; Tower of Glammis; the Alderstone Pippin of East-Lothian, and the Lady Wemyss of Fifeshire. An apple called the French Crab (but which is of considerable size, notwithstanding this name), keeps firm in pulp till the return of the apple season; and the subvariety of this, called Hambledon's, is described in Ronalds' Pomona as still superior.

Some excellent new varieties of apples have of late years been produced both in England and Scotland. Mr Hardy of Bothkennar, by crossing the Court of Wick Pippin with the Nonpareil, has raised seedlings partaking of the good qualities of both parents, and these have received the warmest approval of the Scottish Horticultural Society.

It may be mentioned, that information respecting the fruits cultivated for the manufacture of cider and perry, may be obtained in the Pomona Herefordiensis, published by Mr Knight, and illustrated with engravings by the late Mr W. Hooker. Cider is principally made in Herefordshire and Gloucestershire, which are called the cider counties; but much is also produced in Devonshire. For the encouragement of its manufacture in Scotland, premiums have been offered by the Caledonian Horticultural Society, but little good Scottish cider has hitherto appeared.

Several kinds of stocks are used for apple-trees. The Dutch *Paradise*, propagated by layers, has long been used as a stock for dwarf apple-trees, whether intended for the wall or for standards. The *Doucin* of the French seems closely allied to this, if not identical with it. The bur-knot varieties increased by cuttings, or young codlin plants procured from layers, furnish stocks for the trees from which it is desired to raise new seedlings. For common purposes, the stocks raised from the pips of crabs or of cider apples are preferred. Stocks kept one or two years in nursery lines are fit for grafting upon; but if a considerably tall stem is wished, they must remain three or four years in the nursery, or till they attain five or six feet of height. In the Dutch nurseries, where apple-trees are trained for some years to the cup-shape, the table, the pyramidal, or the round forms, before they are sold to the public, the trees are repeatedly transplanted; but with us, where such forms are less sought after, the utility of more transplantations than from the seed-bed to the nursery lines, and thence to the garden, may, in Mr Knight's opinion, be questioned. Any common soil, provided the subsoil be dry, suits the apple-tree. Shallow planting should in all cases be practised.

The fruit, as in the pear-tree, is produced on spurs, which come out on the branchlets of two or more years growth, and continue fertile for a series of years. There is, therefore, no material difference in the pruning and training of the pear and of the apple tree. On walls, the horizontal mode of training is commonly followed, as best calculated to repress the vigorous growth of the tree; but for the nonpareil, and other twiggy varieties, perhaps the fan-form, or some modification of the fan-form, is preferable. For standards, where the soil is rich and the growth rapid, all that is necessary in pruning is to thin out the branches, and to prevent their crossing each other. Where there is little luxuriance, and in the case of all dwarfs, it is useful to shorten the branches occasionally, and to remove useless twigs. Dwarfs on paradise stocks may be treated almost like currant bushes, to the great advantage both of the size and beauty of the fruit. The winter pruning may take place any time from the beginning of November to the end of March. Cankered or diseased wood, and all unfruitful snags or rugged spurs, are then to be neatly cut out.

If the American blight, or woolly aphis (the *Eriosoma Mali* of Leach) make its appearance on a tree, the utmost care should be taken to clean every part of the bark with a hard brush and some searching wash; for, should the insect be left unmolested, it will speedily spread over all the apple-trees in the neighbourhood. Indeed, the pest is so grievous, that the sacrifice of two or three trees is a small price to pay for its removal.

For the *storing of Pears and Apples*, there should be attached to every considerable garden a commodious fruit-room, well ventilated, furnished with fire-places or stoves to exclude frost, and fitted up with a variety of shelves. A northern aspect is the most suitable; and it is also desirable that there should be a dry, cool cellar under it, to be employed in retarding the ripening of some of the fugitive varieties. All the fruit intended for keeping should be plucked with the hand, or with such an implement as the fruit-gatherer invented by Mr Saul of Lancaster. The finer dessert fruits should be laid on shelves made of hard wood, not of fir, and covered with cartridge or writing paper, to prevent their imbibing any taint from the wood. The kitchen fruit may be kept in layers two or three deep, but not in heaps, and should be occasionally examined, when decaying fruit is to be removed. The *sweating* of apples and pears, formerly much practised, is now abandoned, as being attended with no useful effects.

The Quince (*Pyrus Cydonia*), allied to the apple, is a native of the south of Germany. It is but little cultivated in Britain. The fruit, which is austere when raw, is used to give flavour and poignancy to stewed or baked apples. The two principal sorts are the Portugal Quince and the Pear Quince, of which the latter is the most productive, while it serves the usual culinary purposes equally well as the other. Quinces may be propagated by layers or cuttings, or by grafting. Two or three trees planted in the slip or orchard, are in general sufficient. In Scotland, the fruit seldom approaches maturity, unless favoured by a wall.

The Medlar (*Mespilus Germanica*) is a native of the south of Europe, but has been naturalized in some parts of the south of England. The varieties worth notice are, the Dutch Medlar, with broad leaves; and the Nottingham Medlar, with narrow leaves: of these, the latter is considered the best. The fruit is gathered in November, and kept till it begin to decay, when it is served up in the dessert, and highly relished by some. The treatment recommended for the quince may be applied to the medlar.

The Service-tree (*Pyrus domestica*) is a native of the mountainous parts of Cornwall, and, though not much cultivated, may here be noticed. The fruit has a peculiar acid flavour, and is used only when thoroughly mellowed by keeping. There is a pear-shaped, and also an apple-shaped variety, both of which may be propagated by layers, and still better on seedling plants of their own kind. Two or three trees may have a place in the orchard, or perhaps in a sheltered corner of the lawn. The tree is seldom productive till it have arrived at a goodly age. The fruit is brought to Covent-Garden Market in winter; but it is never seen at Edinburgh. Near Paris, the tree is a good deal cultivated under the name of *cormier;* and there are a number of varieties of the service grown in the north of Italy.

The Mulberry (*Morus nigra*) is a native of Persia, and in this country requires a warm sheltered situation. The fruit is in request for the dessert during the months of August and September, having a rich aromatic flavour, and a fine subacid juice. Where it is abundant, wine is made from it. In Devonshire, a little of the juice added to full-bodied cider, produces a delicious beverage, called Mulberry Cider, which retains its flavour for many months. The mulberry is propagated from cuttings or layers, but, to expedite the production of fruit, it is useful to inarch small bearing branches on stocks prepared in flower-pots. Mulberry standard trees succeed only in the southern counties. These require no other training than an occasional thinning out of the branches. They are generally planted on grassy lawns, so that when ripe fruit falls from the higher branches, it can be gathered without having sustained injury. In the middle districts, espalier-rails may be employed, particularly under the reflection of a south wall. In colder situations, the mulberry must be treated as a wall-tree; and it has been recommended that the bearing shoots should be trained perpendicularly downwards. Mr Knight strongly advises the forcing of this fruit in flower-pots, much in the same way as is done with figs. The mulberry as a fruit is little known in Scotland; but a few aged trees exist in old gardens, and, in favourable seasons, afford their fruit.

The Hazel (*Corylus Avellana*), one of our indigenous fruits, is the original parent of the Filbert, Cob-nut, Cosford-nut, Frizzled, and other improved varieties. These succeed best on a rich, dry loam, carefully worked, and receiving from time to time a slight manuring. They are generally planted in the slips, but thrive best in a quarter by themselves. The varieties are propagated by layers or suckers; but where there are stocks of the common hazel, the other kinds may be grafted upon them. The Cosford is generally preferred, being thin-shelled and having a kernel of high flavour.

The neighbourhood of Maidstone in Kent has long been celebrated for the culture of nuts for the London market; and as the best Kentish practice is scarcely known in other parts of Britain, we may enter a little into detail. The young plants are almost always suckers from old bushes, and are planted about ten or twelve feet apart. They are suffered to grow without restraint for about three years, and are then cut down to within a few inches of the ground. They push out five or six shoots; and these in their second year are shortened one-third. A hoop is then placed within the branches, and the shoots are fastened to it at nearly equal distances. In the spring of the fourth year, all the laterals are cut off close by the principal stems, and from these cut places short shoots proceed, on which fruit is expected in the following year. Those which have borne fruit are removed by the knife, and an annual supply of young shoots is thus obtained. The leading shoots are always shortened about two-thirds, and every bearing twig is tipped. In the early spring pruning, a supply of male blossoms is left, and suckers are carefully eradicated. These Kentish nut-plantations somewhat resemble large quarters of gooseberry bushes, few of their trees exceeding six feet in height. The curious reader may be referred, for additional information, to the paper, on this subject by the Rev. Mr Williamson, in the 4th volume of the Transactions of the London Horticultural Society.

The Walnut (*Juglans regia*) is a native of Persia, and the south of the Caucasus, and the fruit therefore seldom comes to complete maturity, except in the warmer districts of Britain. Besides the common walnut, there are several varieties cultivated, particularly the Large-fruited or Double Walnut, the Tender-shelled, and the Highflyer, which last is said (*Lond. Hort. Trans.* iv. 517) to be "by far the best walnut grown." The varieties can be propagated with certainty only by inoculating; but the operation is rather nice, and not unfrequently fails. Mr Knight's method is described in the London Transactions, vol. iii. p. 133. Plants raised from the seed seldom become productive till they be twenty years old. The fruit is produced at the extremities of the shoots of the preceding year; and therefore in gathering the crop, care should be taken not to injure the young wood. In Kent, the trees are thrashed with rods or poles; but this is a rough, and far from being a commendable, mode of collecting the nuts.

The Chestnut (*Castanea vesca*), like the preceding, has long been an inmate of our woods, in which it grows to a great size; but it seldom ripens its fruit in the northern parts of the island. Several varieties, remarkable for their productiveness and early bearing, have of late years risen into notice; particularly Knight's Prolific, and the New Prolific. These are propagated by grafting upon stocks raised from nuts; and when grafts are taken from bearing wood, fruit may be produced in a couple of years. The tree thrives best on a dry subsoil.

SMALL FRUITS.

The Red, White, and Black Currant, the Gooseberry, the Raspberry, the Strawberry, and Cranberry, are usually cultivated in our gardens, under the title of Small Fruits. Their economical uses in cookery, confectionary, and in the manufacture of home-made wines, attach to them considerable importance, and render a separate, however brief, account of them desirable.

The *Ribes rubrum*, Lin. includes as its varieties our Red and White Currants. The principal subvarieties are:

Common Red,
Red Dutch,
Knight's Sweet Red,
Champagne,
Common White,
Dutch White.

Red and white currants are readily propagated by cuttings. They succeed in any sort of common garden soil; but seem to thrive best in warm moist situations, where they enjoy an abundance of air. A few plants are sometimes placed against walls, on which they are trained perpendicularly. Currants are sometimes planted in single lines in the borders which separate the plots in the kitchen garden; but it is generally better to confine them to compartments by themselves. In these they are arranged in quincunx order, at six feet between the lines, and six feet in the line. They may be transplanted at any time between the fall of the leaf and the first movement of the sap. They are trained *en buisson*, from single stalks of about a foot in height, care being taken to prevent the main branches from crossing each other. In winter the young bearing wood on the sides of the branches is shortened down into spurs, from an inch to two inches in length. The leading shoots are left about six inches long. Some careful cultivators reduce the young shoots to about half their length as soon as the fruit begins to colour, an operation which is found to increase the size and improve the flavour of the berries.

Of *Ribes nigrum*, Lin. or black currant, there are several varieties, of which we need mention only the Common Black, and the Black Naples. The latter is the preferable sort. The black currant thrives in a moist, deep soil, and shady situation. Its culture is much the same as that of the other currants, but the young shoots are not spurred. All the pruning necessary is to keep the branches free of each other, and to promote a succession of young wood.

The Gooseberry.—Botanists distinguish two species: *Ribes Grossularia*, or rough-fruited gooseberry; and *Ribes uva crispi*, or smooth-fruited gooseberry. The gooseberry has always been a favourite fruit in Great Britain, and is said to be produced, in the middle districts, in greater perfection than in any other part of the world. Many very large sorts have originated in Lancashire, where the culture has been carried to a high degree of refinement; but it is to be regretted that *weight* seems, absurdly enough, to be regarded, in the prize competitions, as the sole criterion of excellence. Berries of twenty or even twenty-four pennyweights are boasted of; but such are always inferior in flavour. The following are some of those sorts recommended in the catalogue of the *Lond. Hort. Society*.

Red.—Red Champagne or Ironmonger, Crown Bob, Small Red Globe, Keen's Seedling, Lord of the Manor, Miss Bold, Leigh's Rifleman, Red Warrington, Wellington's Glory.

Yellow.—Yellow Ashton, Yellow Ball, Yellow Champagne, Golden Yellow, Smiling Beauty, Smooth Yellow, Yellowsmith.

White.—Bright Venus, White Champagne, Cheshire Lass, Crystal, White Crystal, White Damson, White Honey, Whitesmith.

Green.—Green Gascoigne, Pitmaston Green Gage, Green Seedling, Langley Green, Late Green, Green Laurel, Gregory's Perfection, Green Walnut.

Some admirable new varieties have of late years been raised in Scotland, particularly in Perthshire: the Delvine Porcupine and Delvine Ironmonger are not surpassed by the finest of the English productions.

In forming his collection, the horticulturist should especially select a few early and a few late sorts, and, by properly disposing the bushes in various situations in his garden, he may prolong the fruit season by several weeks. The same object may be further promoted by defending the late sorts from the attacks of wasps, by surrounding the bushes with bunting (the thin stuff of which ships' flags are often made), and by covering up the bushes with mats. This contrivance, however, answers better with currants than with gooseberries.

The gooseberry-bush affects a loose rich soil, which readily imbibes, but does not retain much moisture. We have seen it succeed perfectly well on little more than pure sand which was free from gravel. It thrives in any common garden soil. Gooseberries, like currants, may be grown in lines or compartments. They are propagated by cuttings, and are transplanted, in open weather, during any of the winter months. They are trained with single stems, from six inches to a foot high; and all suckers, which are apt to spring up from the roots, are carefully removed. Formerly it was the practice in Scotland to spur all the annual wood; but now the black currant system of pruning is more generally and advantageously followed. The ground on which the bushes stand is carefully digged once a-year; and manure, when necessary, is at the same time added. Nothing more is requisite than to keep down weeds, and to prevent the attacks of caterpillars, by picking them off on their first appearance. Gooseberry plants are sometimes trained on walls or espaliers, to accelerate the ripening, or increase the size of the fruit.

The Raspberry (*Rubus Idæus*) is, like the preceding small fruits, a native of Great Britain. The principal varieties are:

Red Antwerp,
Yellow Antwerp,
Barnet,
Common Red,
Cornish,
Williams' Double-bearing.

Of these, the first two have never been surpassed, and are generally sufficient for all common purposes. Raspberries are propagated from suckers, which are planted in rows five or six feet apart, and at three feet from each other in the rows. The fruit is produced on small branches which proceed from the shoots of the former year. Every year they throw up a number of shoots from the root, which bear fruit the subsequent year, and then die. In dressing the plants in winter, all the decayed stalks are cut away, and of the young shoots only three or four of the strongest are left, which are shortened about a third. These, as they are too weak to stand of themselves, are sometimes connected together by the points in the manner of arches, and sometimes they are attached to a stake. Perhaps the best support is obtained by fastening the points of the shoots to a slight horizontal rail or bar about four feet high, and placed a foot and a half on the south side of the rows. By this means the bearing shoots are deflected from the perpendicular to the sunny side of the row, and are not shaded by the annual wood. The ground between the rows is well digged in winter, and kept clean. Fresh plantations of raspberries should be made every six or seven years. The double-bearing varieties, which continue to bear during autumn, require light soils and warm situations. It may be mentioned that the crop of any of the varieties may be retarded by breaking off the points of the bearing shoots at an early period in spring; but, like all other fruits, its flavour is highest when it is allowed to ripen at its natural season.

The Strawberry (*Fragaria*) belongs to the same natural family as the raspberry. Amongst the numerous kinds cultivated in our gardens, botanists have distinguished several *species*, but as these distinctions imply no difference in culture, and as it is difficult to trace them amid the "sportings" of the hybrids, we shall not pretend to enumerate them. Scarcely any plant more readily slides into seminal varieties; and indeed, till lately, in consequence of the irregular prevalence of local names, their whole nomenclature was a chaos of confusion. At the instance of the Horticultural Society of London, Mr Barnet, now of the Experimental Garden, Edinburgh, undertook a revision of the subject, and, with great acuteness and discrimination, has removed much ambiguity, and, as we hope, has finally settled the names of the existing varieties. His paper, which is well worth the perusal of every student of horticulture, is in the 6th volume of the London Transactions. In the second edition of the Catalogue of the Lond. Horticultural Society no fewer than 112 varieties are enumerated. But the following are sufficient, and an asterisk is prefixed to those most worthy of cultivation in small gardens.

American Scarlet,
Coul Late Scarlet,
* Grove End Scarlet,
* Old Scarlet or Virginian,
* Roseberry,
Black Roseberry,
Elton,
* Knevett's,
Sweet Cone,
* Keen's Seedling,

Taylor's Incomparable,
* Old Pine or Carolina,
Wilmot's Superb,
Black Hautbois,
* Large Flat Hautbois,
* Prolific Hautbois.
* Alpine, red and white,
Wood, red and white.

The strawberry plant is propagated from runners or from seed. When runners are employed, they are sometimes planted in autumn, or rather as soon as they have struck root into the ground. Most commonly, however, they are permitted to remain unseparated from the parent plants till spring; a practice which debilitates the old plants, and prevents the earth between the rows from being stirred. As, upon the whole, spring planting seems preferable, it would perhaps be well to adopt the practice of some gardeners, who are at pains to prick out the offsets, as soon as they are rooted, into beds of rich soil, from which they are transplanted into their proper places early in the spring.

The desire of new varieties has encouraged the practice of propagating by seed; and Keen, Knevett, and others, have been extremely successful. Mr Knight having observed that the young runners of the alpine strawberry flower and ripen fruit the first year, was led to adopt this mode of reproduction, and has followed it with the happiest success. Early in spring he sows the seed in flower-pots, which are put into a hot-bed; and as soon as the plants have attained a sufficient size, they are transplanted into the open ground. They begin to blossom soon after midsummer, and continue to produce fruit till they be interrupted by frost. Thus Mr Knight is inclined to treat the alpine strawberry as an annual plant. The same practice has been recommended in France by M. Morel de Vindé (*Cal. Hort. Mem.* vol. iii.), but he very properly preserves his plants for three years, sowing every year a successional crop. Mr Keen has applied this method of culture to the wood strawberry, and we doubt not but it might be extended with beneficial effects to the Old Scarlet and others of the less artificial varieties.

A clayey soil or strong loam is considered as best suited to strawberries. On a sandy or very light soil they seldom succeed; and in close situations, and over-manured ground, most varieties produce little else than leaves. Before planting, the ground is manured and trenched or digged over deeply, and when stiff and compact, is very carefully worked. Keen and others in the neighbourhood of London, grow their strawberries in beds, three rows in each, with an alley between them. The market gardeners of Edinburgh, who, in the culture of this fruit, are perhaps not excelled by any, plant in rows two feet asunder, and from a foot to fifteen inches in the rows. When the weather is dry, the young plants are watered till they be well established. As little fruit is produced the first year, a line of carrots, onions, or other vegetable, is often sown between the rows for one season. In May the runners are cut off, with the view of promoting the swelling of the fruit. During dry weather, careful cultivators water their plants while in flower, and particularly after the fruit is set, and occasionally till it begin to colour. The old practice, from which the fruit derives its name, of putting straw between the rows to prevent the soiling of the fruit, has been recently revived; and where there are lawns, the short cut grass may be employed for the same purpose. As soon as the fruit season is over, the runners are again removed; the straw or grass is taken away, and the ground hoed and raked. In October the runners, the reclining, but *not the erect*, leaves are cut away, and the surface of the earth is stirred with a three-pronged fork, great care being taken not to injure the roots. Strawberries may be raised from the same ground for an indefinite space of time, but the plants should be renewed every third or fourth year. In the garden they are generally put in a quarter by themselves, and it should be one fully exposed to the sun and air. The alpine and wood varieties may be placed in situations rather moist and shady, as edgings in the slips, or in rows behind walls and hedges, in which situations they succeed perfectly well, and produce fruit late in the season.

Strawberries have always been a favourite dessert fruit. They likewise form an excellent preserve; and from their freedom from excess of acid, seem well adapted to the manufacture of native wine. To this purpose they have been only partially employed; but the samples of strawberry wine which we have tasted had more of the vinous flavour, than any other of our home-made wines. The culture of strawberries is the most lucrative part of the employment of the market gardener, at least near large towns. It is not uncommon for him to realize a clear profit of L.30 or L.40, or even more, per acre, of strawberry ground. The greater the diligence and assiduity of the cultivator, the greater will be his returns. It is a common and just remark, that too little labour is, in general, expended upon strawberries, and by the ignorant and unskilful gardener least of all.

Strawberries are easily forced. The Old Scarlet, Grove End, and Keen's Seedling, are most suitable for this purpose. They are potted in April, with rich soil, two or three young plants being put into each pot eight or ten inches in diameter. During summer they are kept in a warm situation and encouraged to grow, the flowers and runners being carefully picked off. In the beginning of winter they are sheltered in cold frames, and are afterwards successively placed into hot-beds or forcing-houses, so as to keep up a succession. The air is kept moist, and they are plentifully supplied with water. Where the means are abundant, a moderate supply of fruit may be maintained during the late winter and the spring months.

Cranberry. The culture of the American Cranberry (*Vaccinium macrocarpon*) was introduced by the late Sir Joseph Banks, and deserves particular notice, for it is altogether overlooked by Lindley and other horticultural writers. The plant is distinguished by the smoothness of its stems, and the largeness of its fruit. It grows freely, and produces its fruit readily in any damp situation; but where there is a pond, it may be cultivated with the greatest success. On the margin of the pond stakes are driven in, a short way within the water line; boards are so placed against these as to prevent the soil of the cranberry-bed from falling into the water. A layer of small stones is deposited in the bottom, and over these, peat or bog earth, mixed with sand, to the extent of about three or four inches above, and half a foot below the usual surface of the water. Plants of the American cranberry placed on this bed, soon cover the whole surface. There is a variety which is very shy in yielding its fruit, and this should, of course, be avoided. From a bed thirty or forty feet in length by five or six in breadth, a quantity of berries may be procured, sufficient for the supply of a family throughout the year. The fruit is easily preserved in bottles. The native Cranberry (*Vaccinium Oxycoccos*) may be treated in the same manner, and in some places is very successfully cultivated. At Culzean Castle, the seat of the Earl of Cassilis, in Ayrshire, the cranberry ground is surrounded by a ditch, the water from which is made to filter through among stones and stakes to the interior, so as to keep the cranberry plants constantly supplied with moisture. In the same garden a second compartment is dedicated to small fruits of this class, having in the centre a rock-work planted with Whortle-berries (*Vaccinium vitis-idæa*), and around the rock-work beds of American Cranberry, of Scottish Cranberry, and of Crowberry (*Empetrum nigrum*), also native.

The following plants produce fruit, some of them abundantly in a wild state; others sparingly in our gardens, but they can scarcely be said to come within the province of Horticulture: *Berberis vulgaris*, the Barberry; *Sambucus nigra*, the Elder; *Prunus spinosa*, the Sloe; *P. insititia*, the Bullace; and *Rubus Chamæmorus*, the Cloudberry.

THE FORCING GARDEN

Is only a department, but an important one, of the Fruit Garden. The term *forcing* is strictly applicable only to those artificial processes by which vegetation is in a considerable degree accelerated; but in common language it has been applied to all those operations in which glazed frames or houses are concerned, though they may be employed merely in aiding the common progress of nature. For the sake of convenience, we shall adopt the term in its broadest acceptation. After some preliminary observations we shall first speak of the structures, and then of the fruits and vegetables which are cultivated in them.

The principal object of hot-houses, and other structures of a similar nature, is to produce an artificial temperature and humidity of the atmosphere, which shall resemble, as nearly as possible, the climate in which the fruits or plants naturally grow. A command of heat is obviously a primary requisite. A regulated admission of air, and the presence of a certain degree of moisture, are in the next place necessary. Lastly, without the free access of light, plants become blanched or are destroyed by the moisture which they generate. These, then, are the conditions which limit the form of hot-houses; when these are attained, any form may be adopted which invention can devise, or wealth execute; but every true lover of the art will aim at simplicity, and will deprecate useless expenditure, so often exhibited in this department, as injurious to the character as well as to the progress of horticulture.

Artificial Heat. Forcing-houses are heated by means of *flues* conveying smoke and heated air; by *pipes* conducting steam or hot-water; by so constructing the glazed house as to increase the action of the rays of the sun; and sometimes by the fermentation of vegetable substances.

Flues are generally constructed of common brick, though occasionally fire-brick is employed in the *neck*, or that part of the flue immediately adjoining the furnace. The bricks in the side walls are placed on their edges, and the top covering is of tile an inch and a half in thickness. In districts where sandstone-flag abounds, the covers are often formed of it. Horticultural writers have recommended that flues should be about eighteen inches deep, and of nearly equal breadth; but to obtain the greatest quantity of heat, it clearly appears from the experiments of Mr Stevenson (*Cal. Hort. Mem.* i. 143), that, where possible, the breadth should be nearly double the depth. It is advantageous to detach flues as much as possible from the walls of the building which incloses them, in order that the heat may be communicated to the air only. Formerly they were often built, sometimes one above another, with only one side exposed, a practice which, as it occasioned great waste of heat from conduction, has been generally abandoned. When it is necessary to lead one flue above another, or to make it return upon itself, spaces should be left between them, to allow the free emission of caloric from every side.

With a view to economy of fuel, can-flues and cast-iron cylinders have been proposed, and occasionally adopted, but their use has not hitherto become general. The arrangement of flues depends upon the nature of the house; it may, however, be remarked generally, that as heated air has a tendency to ascend, they should be placed as near as can be done with convenience to the front of the house, where, of course, the sloping roof is lowest. It is likewise useful to introduce a flue at that part of the structure which is most exposed to any refrigerating influence.

The furnace is most properly situate behind the house, and is generally covered by a shed. For the most part it is constructed so that the upper part of its arch shall be on a level with the top of the flue; but where a considerable heat is required, as in pine stoves, it is found preferable to sink the furnace, in order to produce a *neck* or rise of about a foot and a half in height, which moderates the intensity of the heat on its first entrance, and, by increasing the draught, causes the fire to burn freely. The size of the furnace depends upon the kind of fuel employed. Where coke or charcoal is used, it may be about eighteen inches square; but where small-coal, turf, or peat is to be burned, it should be two feet or even two and a half square, by two feet in height. A large furnace ensures the continuance of the fire, a fact which in practice has received too little attention. To resist the effects of heat, the interior should be lined with fire-brick. The roof should be strongly arched. The door may be about a foot square, and when it is double, as it ought always to be, the outer half should be a little larger than the inner. The grate is of the same breadth as the door, and may extend about two-thirds of the length of the furnace. The ash-pit is equally wide, and from fifteen to eighteen inches deep; it is furnished with a ventilator in the door to regulate the admission of air. In practice the furnace, and especially the ash-pit, should be kept clear of ashes; as by this means, coals of an inferior quality may be burnt with ease. We know an instance in the neighbourhood of Edinburgh, where a number of large furnaces were maintained for several years by the mere refuse of a coal-yard attached to the mansion of a considerable family.

In Plate CCXC. fig. 1 and 2, are given a longitudinal section and plan of the common garden furnace. It is surrounded by a double wall to prevent the escape of heat.

Mr Witty has invented a new furnace, which is possessed of valuable qualities. A vertical section of it is given in Plate CCXC. fig. 3. The fuel is supplied by the door at *a*, and is pressed down the inclined plane towards the grate *c*, by an apparatus placed at the head of it; but this method being complicated, has given way to several modifications, in which the door *a* has been found the most useful, the fuel being pressed forward by the common tools used for feeding furnaces: *b* is the door for regulating the fuel on the grate *c*. In its progress, the whole surface of the coal along the inclined plane is constantly kept in a state of inflammation, the flame having naturally a tendency to burn upwards. In this way the greater part of the fresh coal is carbonised, that is, the gas is separated from it and inflamed, leaving only coke. The strong combustion of the coke at the grate produces heat enough to carbonise the coal, and air enough to inflame the gas. This furnace, therefore, not only consumes the smoke, but effects a considerable saving of fuel.

Steam. Of late years steam has been applied with success to the production of an artificial climate in glazed houses. It is more genial than fire-heat from flues, being less contaminated, and more equable and pliant in its distribution. In steam hot-houses the plants can scarcely ever be liable to suffer from scorching heat; the air continues pure and untainted, and persons visiting the house are much less liable to be annoyed by the smell of smoke and soot. It is neater in all its arrangements within doors, and precluding, without, the necessity of more than one furnace, and one chimney top, in a great measure removes the unseemliness of the heaps of coals and ashes with which common furnaces are usually surrounded. In districts where coals are dear, the saving of fuel is an object; and it has been found that seven bushels of coals go as far in keeping up steam heat, as ten bushels do in maintaining an equal temperature in the ordinary way. By merely opening a valve, the house may at any time be effectually *steamed*, that is, filled with the steam or vapour, and the warm moisture thus applied to the plants, is observed to contribute remarkably to their health and vigour. To counterbalance these advantages, we are not aware of any defects, except such as may arise from the greater complexity of the apparatus, or at least its liability to disrepair and accident.

Steam is generated in a cast or wrought iron boiler, of an oblong form, furnished with safety-valves, and heated by a smoke-consuming furnace. As in the common steam-engine, the boiler is supplied from a cistern above, and is made to regulate itself by a simple contrivance. In the feed-head is a valve, which is opened by the sinking of a float, which descends in proportion as the water is dissipated in steam; and, being balanced by a weight, whenever a sufficient quantity of water is admitted, rises again, and shuts the valve. As steam may be conveyed, without materially impairing its calorific powers, to the distance of several thousand feet, one boiler is sufficient for heating all the glazed houses which are ever erected together; but a second is generally kept in readiness, to act as an auxiliary in case of accident, or in very severe weather. Steam is conducted from the boiler in a single main pipe, or in two parallel pipes, which, according to Mr Tredgold, may be only one inch in bore. The divarications of the pipes into particular houses are arranged somewhat in the manner of flues, and, indeed, are sometimes placed within these, or on them, when they already exist, as in Plate CCXCIII, fig. 3, below the passage *d*. These interior pipes are from three to six inches in diameter, in order to afford a greater radiating surface, and are supplied with sets of valves to admit, regulate, and exclude the heated vapour, according to circumstances.

The most perfect and extensive examples of steam-apparatus exist at Syon-House, the princely seat of the Duke of Northumberland, near Brentford, and in the nursery-garden of Messrs Loddiges at Hackney. At the latter place, glazed houses, to the extent of almost a thousand feet in length, and forming three sides of a square, are heated solely by steam from one boiler. The boiler is of an oblong shape, measuring eleven feet by four, and is made of malleable iron. In certain narrow houses, intended by Messrs Loddiges for greenhouse plants, a single steam-pipe is found sufficient. In other houses of considerable height and breadth, or where a higher temperature is required, as in the palm-house, the steam flue is made to describe two or three turns.

Water, contained in large vessels or pipes, is sometimes heated by steam, and so made the medium of conveying caloric to the atmosphere of glazed houses. Fig. 13, Plate CCXC., represents an instance of this arrangement. A small steam-tube, one inch in diameter, enters a water-pipe eight inches in diameter, and twenty-eight feet long, wholly within the forcing-house; it passes into the larger pipe at the centre, and after traversing its whole length and returning, it issues out immediately below the point at which it entered. It then forms a siphon, by which the condensed water is conveyed away. A more detailed description may be found in the *Lond. Hort. Mem.*, vol. iii. Applications of it are given in Plate CCXCII., fig. 6, *a*, and Plate CCXCIII., fig. 3, below the passage *c*.

Steam is sometimes employed to furnish bottom heat. In the garden of Mr Sturge, near Bath, a shallow cistern of water is heated by a steam-pipe, in the manner exhibited in Plate CCXC., figs. 15, 16. The cistern is covered with pavement, over which is a bed of small stones, then ashes or sand, into which the pots containing plants are to be plunged.

Steam has also been employed to heat flues. Plate CCXC., fig. 14, is a side view and section of a flue filled with small stones or broken bricks, and heated by means of a small steam-pipe passing along the lower part of the flue. Along the upper side of this pipe are a number of small holes, becoming more frequent towards the farther end, to allow the escape of steam: there are, besides, a few perforations in the under side, to clear away condensed water. The flue has a slight inclination to that end of the house from which the water can be most easily drained.

Similar expedients were long ago employed, in the heating of forcing pits, by Mr John Hay of Edinburgh, a garden-architect of great judgment and experience. Plate CCXC., figs. 17, 18, represent a recent variety of this mode of supplying surface and bottom heat, by discharging steam into flues and chambers filled with stones. The steam is admitted by small pipes running along the central pit, in channels about four inches deep, and of the same width. These channels are crossed by others at right-angles; and at the points of intersection the steam is permitted to escape by two small holes, one on each side of the pipe. The pits must have a water-tight paved bottom, with a declivity of one inch in ten feet. The sides and covers of the channels are loosely jointed, and are permeable by the steam. Stop-cocks are attached to the pipes, so that the supply of vapour can be adjusted. Another mode of adapting steam to the production of bottom heat, may be seen in Mr Macmurtrie's Pine-Pit, to be afterwards described.

Hot Water. More recently the circulation of hot water in iron pipes or vessels has been successfully employed in producing artificial warmth. The temperature derived from this source has all the properties of steam-heat, with these additional advantages, that it is more steady, not being liable to interruption by the bursting of vessels, and more lasting, as water does not cool so rapidly as aqueous vapour.

The following explanation of the principle of the hot-water apparatus is given by the late Mr Tredgold, in an excellent paper in the *Lond Hort. Trans.* vol. vii. "We may select the simple case of two vessels placed on a horizontal plane, with two pipes to connect them; the vessels being open at top, and the one pipe connecting the lower parts of the vessels, and the other the upper parts. If the vessels and pipes (Plate CCXC., fig. 4) be filled with water, and heat be applied to the vessel A, the effect of heat will expand the water in the vessel A; and its surface will, in consequence, rise to a higher level *a*, *a*, the former general level being *b*, *b*. The density of the fluid in the vessel A will also decrease, in consequence of its expansion; but as soon as the column *c*, *d*, of fluid above the *centre of the upper pipe* is of greater weight than the column *f*, *e*, above that centre, motion will commence along the upper pipe from A to B, and the change this motion produces in the equilibrium of the fluid will cause a corresponding motion in the lower pipe from B to A; and, in short, the motion will obviously continue till the temperature be nearly the same in both vessels; or if water be made to boil in A, it may also be boiling hot in B, because ebullition in A will assist the motion."

The figure referred to in the preceding quotation, representing the common tank boiler surrounded by a flue, with a cistern at the extremity of the pipes, exhibits the form in which the apparatus was first erected; but as in this arrangement the process of heating was very slow, and many changes have been made, the cistern has generally been abandoned, and boilers of various configurations have been adopted. In fig. 5, Plate CCXC., a longitudinal section, and in fig. 6, a transverse section, are given, of a flued tank boiler, in which the surface exposed to the heat being increased, the effect required is accelerated, and at the same time a considerable saving of fuel is effected. Fig. 7. represents a section of an oblong, close, semi-cylindrical boiler, in which the action of the fire is still more increased. Fig. 8. is a section of a greenhouse boiler, constructed by the Shotts Foundry Company. The fire is placed entirely within the lower curved surface. This form is easily heated; but as there is no surrounding brick-work or masonry, it speedily cools. It is unnecessary to describe all the numerous modifications of this apparatus; but it may be proper to direct the attention of the reader to the close boiler, fig. 9, in which is shewn how the circulation may be conducted over a door or other obstacle. In this case the upper pipe must not ascend and descend twice: air-tubes ought also to be placed in a boiler, and on the highest part of the pipes; and the whole must be made considerably stronger than on common occasions. Fig. 12. is an isometrical elevation of a hot-water apparatus, for a vinery thirty feet long by eleven wide. A is the boiler, as in figure 4; B the upper or delivering pipe; C the principal part of the upper pipe, of a flat form, presenting a greater radiating surface, in proportion to the quantity of heat; D the descending limb; E the returning pipe, of a cylindrical form.

Mr Fowler has employed the siphon as a part of the hot-water apparatus; and in his tract on the *Thermosiphon*, as he calls it, has shewn how its various modifications may be employed in warming hot walls, as well as in heating glazed houses. The following statement of the principle is given in the Gardener's Magazine, vol. v. "Any one may prove that hot water will circulate in a siphon, by taking a piece of lead pipe, say of half an inch bore, and four or five feet long, bending it like a siphon, but with one leg a good deal more bent than the other, in order to give the descending water time and space for giving out its heat; and then, filling this tube with water, and placing one hand on each end to retain it full, immerse the extremities in a pot of water over a fire, (Plate CCXC., fig. 11). Supposing the water of an uniform temperature in both legs of the siphon, no circulation would take place; but supposing it to cool sooner in the long leg *a* than in the short leg *b*, then the equilibrium would be destroyed, and the water in the long leg *a* would descend, and draw up water through the short leg *b*; and this circulation would continue as long as the water *c* was maintained at a temperature above that of the surrounding atmosphere."

Mr Kewley's adaptation of the siphon is one of the simplest and most efficient that has been proposed. In Plate CCXC., fig. 10, *a*, *c*, *e*, are the two legs of a siphon, through the upper of which the heated water ascends, and by the lower descends. Immediately over the descending bend, a pipe connected with an air-pump is inserted, in order to fill the pipes, or remove the air which collects in the superior limb. Instead of the air-pump, a funnel with air-tight valves is sometimes employed. This mode of circulation has been adopted in some of the principal nursery-gardens near London.

Mr Charles H. J. Smith, in a communication to the Scottish Horticultural Society, has clearly shewn that the system of heating by the circulation of hot water in metallic pipes, is easily applicable, not only to any glazed house constructed with flues, but to any select portion of an existing fruit-wall, although already clothed with peaches, vines, or figs. In the last case, a small furnace and boiler are, of course, placed at the back of the wall; the expanding water rises to a cistern near the top of the wall; horizontal pipes, making three or four turns, are inserted into the south front of the wall (which is an easy operation, as the wall is usually faced with brick); and through these the water circulates, to the great increase of the temperature of the air surrounding the tree. The operation should be accomplished late in the autumn; the tree being carefully unnailed, bent forward, and secured from breaking, and as carefully replaced.

Mr A. Perkins has constructed an apparatus of small tubes hermetically sealed, in which water circulates, of a temperature varying from 300° to 400° Fahrenheit. The contrivance is very ingenious, and has been pretty extensively employed in the neighbourhood of London, in heating warerooms: but as the opinions of horticulturists respecting its merits, as applicable to the forcing garden, are still divided, and as it has not as yet stood the test of much experience, it may be sufficient to give it this cursory notice. For further information, however, we may refer to the Gardener's Magazine, vols. viii. and ix.

To mention *the rays of the sun* amongst the sources of artificial heat, may excite a smile; yet it happens that, from the stagnation of air, the reflection of light from walls, and other circumstances, they often produce a very considerable proportion of the increased temperature of a hot-house. This species of heat, however, is materially affected by the admission of the air necessary to the growth and healthy state of the plants. We are not aware of its having been employed as a primary source of heat, except in the case of Dr Anderson's patent hot-house, in which heated air was kept, bottled up as it were in separate chambers; an arrangement too irregular and unmanageable to be of much utility in our variable climate.

Vegetable substances in a state of fermentation evolve a considerable quantity of caloric, and are much employed to produce *bottom heat* in hot-beds, pine or melon pits. In a few instances they have been applied to warm the atmosphere of vineries and peach-houses, in which, however, they have been found to be a poor substitute for the other means already explained.

In the management of artificial heat, some degree of caution is required. All the operations of nature are gradual; and in *forcing*, it is well to follow these as the safest examples. The judicious gardener will therefore apply his heat very gradually at first; he will increase it by degrees for several weeks, and, in particular, he will guard against any sudden decrease of warmth, as nothing is more necessary to success than that the course of vegetation be continued uninterruptedly through foliation, inflorescence, and fructification. He will cause the temperature to increase by day and decrease by night, to rise in summer and fall in winter. He will, in short, imitate as much as possible the natural and varying influence of the sun.

The admission of Air.—The deteriorating influence which all living plants are supposed to exert on the atmosphere, must operate with tenfold force in a glazed house, where the proportion of air to vegetable substance is infinitely smaller than under the open sky, and where the corrective agitations of the wind, and the changes of temperature, are much less perceptibly felt. The respiration of plants, and the exhalations of putrescent vegetables, require a constant circulation of the aërial fluid, and this is maintained by means of moveable sashes, and ventilators in the roof of the house. Of these, sashes seem preferable, as less apt to produce cold currents of air, which are always injurious to vegetation. It is, indeed, a disadvantage that, by sliding down over one another, they diminish the influx of light. In winter, however, when light, from its scarcity in our high latitude, is most valuable, they are seldom drawn down to any extent; and by having all the sashes moveable, the gardener, with a little attention, may correct, in a great measure, any inequality in this respect. Sliding sashes require a depth of rafter which greatly augments the shade in oblique sunshine, an evil which cannot easily be obviated. With fixed roofs, and more especially those which are curvilinear (to be immediately described), numerous ventilators are the only means by which a proper circulation of air can be obtained. Some very intelligent gardeners prefer having all the sloping sashes fixed, and ventilate chiefly by means of large windows at each end of the house, aided by small ventilators in front.

The quantity of air to be admitted from time to time, must vary with the season, the temperature required to be kept up, and the kind of plants cultivated. It should be given and withdrawn by degrees, particularly in the colder portions of the year. The sashes or ventilators, for instance, may be partially open by eight A. M., top air being given before front air; full air may be allowed about ten; a reduction should take place before three P. M., and the whole closed between four and five in the afternoon. In summer less caution is necessary, as in many cases the external air differs little in temperature from that within the house. Most commonly air is given only during the day, and is excluded at night, with perhaps an increase of fire heat. Judicious horticulturists will sometimes reverse this process. Knowing, for example, that in the West Indies chilly and cold nights usually succeed the hottest days, they will imitate nature, by shutting up the house by day, and throwing it open at night. This practice, however, supported as it is by analogy, is subject to many limitations, and can only be followed in our climate during the summer and autumn months. It is useful, notwithstanding, to remember the principle, though it admits only of partial application.

The admission of Light.—In addition to the heat with which natural light is always accompanied, there seems to be another property necessary to vegetation which, from some cause hitherto unexplained, is partly deranged by its transmission through glass. The fact, however, is evident, from the circumstance that plants thrive better near glass than at a distance from it, though the intensity of light is apparently undiminished. Hence gardeners have been anxious to distribute their finer plants in situations as close as possible to the roofs of hot-houses.

Connected with the admission of light, is the determination of the pitch or angle of elevation of the roofs of glazed houses. It is evidently of advantage that the rays of light should fall upon glass perpendicularly, as loss by reflection is then a minimum, or indeed little or nothing.[1] The angle necessary to obtain this result is easily deducible from the sun's place in the ecliptic. At the equinoxes, the sun's meridional height above the horizon, at any point of the earth's surface, is equal to the complement of the latitude of that place; and hence, in order that the sun's rays may be perpendicular at that period, it is only necessary to make the elevation of the roof of the hot-house equal to the latitude of the place. The angle for any other season may be obtained by subtracting, from the latitude, the declination of the sun, if at that time to the north of the equator, or by adding it, if to the south. These periods are of course selected in accordance with the time at which the direct rays are most required. Mr Knight proposes a general elevation of 34° for the latitude of London, an angle which corresponds to the 20th of May and the 21st of July. This would afford four months, from the 20th of April to the 21st of August, during which the angle of incidence at mid-day would not at any time amount to 9°, while the deviation at the winter's solstice would be 43°, and the loss of light from reflection would be little more than $\frac{1}{30}$. The Rev. Mr Wilkinson recommends 45°, a pitch extremely suitable for early vineries and pine-stoves. In this case the midsummer deviation would be 19°, and the loss $\frac{1}{40}$, and the midwinter deviation 30°, while the loss is nearly the same. From these statements, however, and from an inspection of the table already referred to, it is manifest that much greater exactness has been required in this matter than is at all necessary. The reduction of the opacity of the roof, arising from the breadth and depth of rafters and astragals, is of much greater consequence. Accordingly, in some glazed houses, particularly those constructed of metallic substances, rafters have been omitted altogether; but this kind of structure leads to considerable difficulties in the admission of air.

We have taken it for granted that the frame-work is composed of wood; and if prime Baltic timber be procured, it will endure for nearly half a century. But in some cases rafters and sashes made entirely of metal, generally either malleable or cast iron, have been employed; and in others, a middle course has been steered, by adopting wooden mortices and metallic tenons. The great objections to the use of metal for rafters and sashes is, that it is too rapid a conductor of caloric, and too liable to contraction and expansion for the alternations of heat and cold; the expansion tending to render the sashes immoveable, and even to loosen the walls; and the contraction being apt to fracture the glass, and to produce openings between the sashes at which hoarfrost may enter.

In order to secure the greatest possible influx of light, scientific horticulturists have proposed hot-houses with curvilinear roofs. It was remarked by Sir George Mackenzie, to whom the merit of the proposal is primarily due, that if we could find a form for a glass roof, such that the sun's rays should be perpendicular *to some part of it*, not on two days, but during the whole year, that form would be the best. Such a figure is the sphere, and he therefore proposes a quarter segment of a globe or semidome, the radius of which is about fifteen feet. The frame for the glass-work is formed of equal ribs of hammered iron, fastened into an iron plate in the parapet wall, and fixed at top into an iron ring connected with the back wall. There are no rafters or sliding sashes, but air is admitted by ventilators in the parapet and back walls.

This form of hot-house roofs has been warmly patronised by Mr Knight, who, however, is of opinion, that the house proposed by Sir George Mackenzie is too high in proportion to its length and breadth, and therefore recommends a smaller section of a sphere with a greater radius. His dimensions are forty feet long, fourteen wide in the centre, and, including the front parapet, twelve feet high. Mr Loudon, who, it is understood, was the first that actually erected hot-houses on this principle, has proposed, and in part executed, many other forms. He describes (*Encyc. of Gard.*) with great exuberance of invention, the *acuminated semidome*, the *acuminated semiglobe*, the *semiellipse*, and the *parallelogram with curved roof and ends*. With Mr Loudon we should certainly prefer the last mentioned. A considerable number of curvilinear houses have been erected in the southern part of the island, particularly as repositories for ornamental plants, such as in Messrs Loddiges' nursery-gardens at Hackney, the London Horticultural Society's garden, the Manchester Botanic Garden, and in various private gardens.

As far as we are aware, no extensive experimental investigation of the comparative merits of curvilinear houses has hitherto been made. A writer in the Gardener's Magazine (vol. ii.) found it necessary, during the summer months, to shade his pines growing in such a house, from nine, ten, or eleven o'clock in the morning, to three, four, or five in the afternoon, in order to prevent the plants from assuming a rusty tinge and unhealthy appearance. Another practical gardener complains (vol. v.) that " the circular

Forcing Garden.

roof concentrated the sun's rays so immoderately, that the tops of the vines were actually scorched, even when the doors and ventilators at the back were all open. This was always the case in summer; and in winter, it was with the greatest difficulty, and only with the assistance of mats, that they could keep out frost; the thermometer frequently indicating only 40° when strong fires were burning." A considerable portion of the superior lightness of the curvilinear houses is due to the absence of rafters, and as these may also be dispensed in plain roofs, the effect of these ought to be deducted in making a comparison. Perhaps, when every thing else is rightly arranged, there is enough of light in common houses. Scarcely any species of fruit, when cultivated in the open air, is exposed during the whole day to the action of the solar rays, but must unavoidably be shaded at times by leaves and branches. It is difficult to suppose that, in respect to illumination, there is any remarkable deficiency in pits and glazed houses, in which have been ripened pine-apples and clusters of grapes, at least rivalling, if not surpassing, the produce of the most favoured of their native climes. In the admission of air, in the quantity and convenience of trellises, and in other interior accommodations, it cannot be disputed that the old forms have the advantage.

It has already been said, that hot-house roofs of the common kind, are sometimes constructed without rafters or moveable sashes. A considerable increase of light is thus obtained; but this benefit is attended with an almost insuperable defect, namely, the difficulty of producing a free and equable circulation of air. It is indeed probable that the common or plain roofed hot-house will always continue the favourite form with gardeners. In it the rafters are arranged at equal distances, and are made of a deep and narrow form, with their under edges rounded off. Nicol recommends that they should be made two and one-fourth inches broad, by ten inches deep. Perhaps they might be a little broader and shallower with advantage. The size of the sashes depends on the magnitude of the house; their breadth, however, ranges from three and a half to four feet. Except in very large houses, sashes are always disposed in two tiers, the upper row sliding down over the under one. Where there are ventilators in the front wall or upright glass, the sashes in the upper tier alone require to be moveable, and, for the sake of convenience, they may be made considerably shorter than the others. They are furnished with cords, pulleys, rollers, and weights, though the last, with no very prudent regard to economy, are sometimes omitted. Formerly all hot-houses were constructed with upright sashes in front. One of the most eminent garden architects of the present day (Mr Atkinson), has discontinued the practice; and, except in ornamental structures, it is hard to say why it should not be laid aside altogether. Such sashes serve only to weaken the fabric, and increase its expense.

Formerly the panes of glass employed were of large size; but small panes are found to be more economical, being less liable to break, and more easily replaced. It is believed that a pane seven inches in breadth by six in length, is the cheapest form in which glass can be obtained. In glazing, it is important to keep the overlaps of the panes of small dimensions, perhaps from one-fourth to one-eighth inch in breadth. This diminishes the breakage which arises from the expansion, in freezing, of the water detained between the laps by capillary attraction. As a further preventive, the interstices are sometimes filled with putty, and occasionally with laps of lead or copper. This effects a considerable saving of glass and of heat, but imposes on the gardener the duty of increased attention in preventing the stagnation of air. The frame-work of houses should be well coated with oil-paint; the colour is usually white.

In closing these preliminary remarks, it is proper to observe, that although the construction of a forcing-house is always a matter of considerable importance, it is not the only, nor even the most important condition necessary to ensure success. Much care in management, skill in pruning, and knowledge in physiology, must be possessed and applied, in order to obtain abundant and regular crops of fine fruit.

The more minute details respecting the structure of glazed houses, we shall notice along with the peculiar culture required in each; and we shall take them in the following order: The Vinery or Grape-house, the Peach-house, the Cherry-house, the Fig-house, the Pinery, the Orangery, and the Melonry. The greenhouse and other botanical structures, will come more appropriately under review in treating of the Flower Garden.

The Vinery. *Structure.*—The vinery is susceptible of a great variety of form; and, indeed, in this respect, seems more pliable than any other forcing-house. That form, however, which has been most commonly used, is the plane roof with sliding sashes; and such is the success with which it has been employed, and such its convenience for every purpose, that it is not probable it will soon be generally supplanted. The section of the Peach-house, Pl. CCXCI. fig. 4, will give an idea of the usual configuration of the vinery. Fig. 3. of the same plate is a section, and fig. 6. a ground plan of a curvilinear vinery, heated by hot-water. A vinery, with flues and two furnaces, is generally fifty feet long, twelve or fourteen wide within, the height of the back wall being ten or twelve feet. Where there is only one furnace, or where a hot-water apparatus is employed, the length of the house should not exceed thirty-five or forty feet. Small divisions are to be preferred; for where there is a considerable extent of glass, the cultivator, by applying his fires to the different divisions in succession, can prolong the crop from May to December. The parapet wall in front is commonly arched or built on lintels, supported by stone pillars; so that the vines, which are planted inside the house, close by the parapet, may send abroad their roots in search of nutriment. Sometimes the vines are planted without, and introduced into the house by slanting apertures in the front wall; but the former method, where possible, is the more eligible. The trellis used for training, is generally formed of wires drawn across the rafters, at the distance of a foot from each other. Of late the trellis has been divided into portions of a moderate breadth, which are placed vertically under the rafter. This form, exhibited in fig. 1, Plate CCXCI., is called the hanging trellis, and is described at length in the *Lond. Hortic. Trans.* vol. vi. It leaves the middle of the sash open to the sun's rays, and allows the back wall to be covered with bearing wood, a thing which, in other circumstances, can scarcely be done with any beneficial effect. It must, however, be admitted, that, according to the experience of some, this arrangement is inferior to the common trellis.

It is of importance that the included soil and front border of a vinery should be fresh and rich, and of a considerable depth. Mr Griffin (in *Lond. Hortic. Trans.*) recommends as a compost, "one-half of good loamy soil with its turf, one quarter of rich old dung, and one quarter of brick and lime rubbish; the turf well rotted, and the whole well incorporated." Plants raised from cuttings, and prepared for two or three years in pots, are preferred for the furnishing of a vinery; and when planted inside the house, there should not be fewer than two plants to each sash.

It is scarcely necessary to enumerate the particular varieties of the grape-vine, as adapted for a vinery, for every good variety deserves a place where there is room, and all those which have been already mentioned are occasionally planted. It may be remarked, however, that the kinds should be assorted according to the order of their ripening.

The early grapes, such as the Muscadines, should be planted in a house by themselves; those of a medium character, the Frotignacs, for example, may occupy a second; while the late Tokay, the Muscat of Alexandria, Nice, Syrian, and others, would be fit inmates for a third. This would produce a regular succession, and admit a uniformity of treatment in each house. Where there is not a suite of vineries, but only one large house, the late varieties should be planted near the entrance of the flues.

Pruning and Training. Very numerous have been the directions given in reference to these particulars; but we cannot here go into such details, nor is it necessary. The great object is the reproduction of bearing, that is, annual wood, over the whole surface of the house. When this is accomplished, the next matter to be determined is the number of eyes or buds to be left on each shoot, that is, whether we shall adopt the *short* or the *long* system of pruning. The former is most allied to the practice of foreign vineyards, and has been most successfully employed in this country. According to this method, all the lateral shoots are cut down to single eyes, as described in *Lond. Hortic. Trans.* iv. 104. For a particular description of the *long* system, we refer to the same vol. p. 246, or to Loudon's Encyclopædia of Gardening, second edition, p. 548. To these references, we add a few general remarks. (1.) In this country, it ought to be the great aim of the gardener to make his vines grow as luxuriantly as possible; for the quality of the grapes, when properly ripened, is generally commensurate with the size of the berries. The borders should therefore be made rich; but they ought to be rather wide than deep, deep planting being adverse to the ripening of the fruit. (2.) In order to secure a proper degree of vigour, vines should be limited in extent, and pruned rather severely than otherwise. To enable us to circumscribe the plants, it would be well to introduce as many separate plants into the vinery as can be done without confusion. For an illustration of this principle, we may refer to the practice of the *vignerons* of Fontainebleau, as described in the *Pomone Française*, or in the *Lond. Hortic. Trans.* vol. vii. (3.) From the peculiar mode of growth in the grape-vine, the bearing branches have a tendency to recede from the centre to the extremities, and are often found in abundance only at the top of the trellis. Every young shoot near the front of the house should therefore be carefully husbanded, and cut back by way of reserve. Old wood ought to be removed as frequently as possible; and the skilful pruner will look at least two years before him. Nothing contributes more to regularity in the succession of bearing wood, than simplicity in pruning and training; and therefore all bending, and twisting, and traversing of branches should be avoided.

The summer pruning consists in removing with the fingers the useless lateral shoots, and pinching off the tender points of the bearing branches. The extent to which these bearing branches are allowed to run will depend on their vigour, and the position which they hold in the plant. Sometimes it may be needful to leave them ten or twelve feet long, but, in general, two or three feet will be sufficient. The shorter the better. They seldom or never fail to send out secondary laterals from their points: these and the others which succeed them are stopped at the second or even first eye, and the operation is continued until vegetation ceases. When the young grapes begin to swell, the bunches are thinned out, that is, berries are removed wherever they are too much crowded together; and the shoulders or sides of the bunches are supported by slender threads of bass-mat. The quality and weight of bunches should be regarded rather than their number. Nothing seems more contemptible than numbers of small and ill-ripened bunches of grapes, smeared, as they frequently are, with dust and honey-dew. Avarice not unfrequently cheats itself in this matter; and it generally happens in the vinery, as elsewhere, that not he who desires most has most. The ripening, colour, and flavour of grapes on the tree are promoted by removing a portion of the foliage; this is to be done, however, only after the fruit has attained full size.

The forcing of the earliest vinery may commence in January. At first the temperature may vary from 50° to 55° Fahrenheit in the mornings and evenings. When the buds have burst, it may be raised to 70°, and in the flowering season it may be kept at 75°. At this season it is necessary that the air should be preserved moist by frequent steamings. Upon the appearance of colour in the fruit, the waterings cease, and air is copiously admitted. In the early vineries, it is necessary to continue the fire-heat without intermission: in the later houses this is not required, but it must be used occasionally, even in warm weather, to obviate the effects of damp.

The PEACH-HOUSE.—A peach-house, intended to be commanded by one furnace, is generally about forty feet long, ten or twelve feet wide, and fourteen feet high; but these dimensions may be varied considerably, according to the time at which the crop is desired to come into season. For early forcing, perhaps twenty-five or thirty feet in length, and seven or eight in breadth, are sufficient; while a house, in which the operations of nature are only to be slightly accelerated, may be extended to fifty feet. As in the vinery, the front wall is arched, to permit the egress of the roots. Upon this is usually placed a range of upright sashes, which are surmounted by the sloping rafters of the roof. A common form of a peach-house is represented in Plate CCXCI., in which fig. 4. is a vertical section, and fig. 5. is the ground plan; *a*, *a*, are the flues, *b* is the table trellis, *c* the trellis on the back wall; along with which, a hanging trellis, as in fig. 1, is sometimes employed, although this is not approved of by many. The flue, which is built on pillars, and returns on itself, occupies the centre of the house. The trees are trained to the two trellises *b* and *c*, and to the hanging trellis, if such be in use. Against the back wall three or four dwarf trees are planted, with intermediate *riders*, the latter being taken out at the end of four or five years at furthest. These, with three for the front trellis, make in all nine or ten trees for each house.

Plate CCXCII. fig. 1, represents another form of the peach-house, not so generally used as the former, but of equal if not superior merit. We have supposed it heated by a water apparatus *a*, *a*, but that is not an essential matter, as a common flue is equally admissible. There is no front glass, nor any trellis on the back wall, the trees being planted in front, and trained on a wire trellis *b*, attached to the rafters, and covering the whole surface of the roof. As the peach-tree is not found to extend much more than twelve or thirteen feet on the open wall, the length of the rafter, inside measure, need not do more than approach to fourteen feet. It is obvious that in such a house the trees must enjoy an equable, and, from their proximity to the glass, an advantageous degree of light. Besides being planted close to the front wall, they are not exposed to have their roots stunted in passing under flues, and through the interior soil of the house, which, in spite of every assiduity in watering and manuring, becomes hard and impoverished. Further, it has been estimated, that as far as roof and glass are concerned, four or even five such houses may be erected, at the same expense as three of the common form.

In Holland, peaches are forced in pits resembling the common hot-bed or melon-pit. The trees are trained on a trellis-work near the glass, and the air is heated by the fermentation of dung-linings. The method has been partially adopted in this country, with, however, the use of hot water. When garden-architects shall cease to be anxious about making all forcing houses ornamental structures, this will probably be the general form in which early and tender peaches will be cultivated.

The pruning and training of peach-trees in the peach-house does not differ materially from the practice out of doors. Fire-heat is commonly applied about the beginning or middle of February; but where there is a large suite of houses, and an extended succession is wanted, forcing, as it then truly becomes, may begin a month sooner. At first the temperature is kept about 45°, but it is afterwards gradually increased to 50° or 55° Fahrenheit. While the trees are in flower, and till the fruit be set, the house is occasionally steamed, either by sprinkling water on the warm flues, or by admitting the vapour from the pipes, where steam is employed for heating. After this period, the foliage is washed, from time to time, with the garden-engine. When the fruit has stoned, or the kernels have been formed, the temperature is raised to about 60°. Water is now copiously supplied to the border; the fruit is thinned out; the various operations of disbudding and tying are performed, and air is admitted in abundance. After the end of April, little fire-heat is required for the peach-house. The trees often suffer from mildew: the best preventives consist in keeping the borders of the peach-house clear, and in good condition as to fresh soil, and in observing that nothing be permitted to obstruct the free circulation of air and full admission of sun.

It may here be remarked, that by curious cultivators several uncommon kinds of exotic fruits are occasionally grown with success in conservatories, vineries, hot-houses, or other glazed structures, along with the more regular or usual inmates. Among these may be mentioned the Loquat, *Eriobotrya japonica;* the Jamrosade *Eugenia jambos;* the Purple Granadilla, *Passiflora edulis;* the Granadilla vine, *P. quadrangularis;* the May-apple, *P. incarnata;* the Water-lemon, *P. laurifolia;* and the Sweet Calabash, *P. maliformis;* the Papaw, *Carica Papaya;* and the Banana, *Musa sapientum.* The Leechee, *Nephelium Litchi,* has ripened in our stoves; the Long-yen, *Euphoria longana,* has yielded its fruit at Syon-House; and the Mango, *Mangifera indica,* at the garden of Earl Powis. The China Guava, *Psidium cattleianum,* fruits freely in the vinery of the Experimental Garden at Edinburgh: the fruit is round, about the size of a small plum; of a fine claret colour; the pulp soft, only a little firmer than that of a strawberry, and of a delightful subacid flavour, making a most desirable preserve. The Carambola, *Averrhoa Carambola,* of the East Indies, has of late been added to our exotic fruits, by Mr Bateman of Knypersley, near Congleton: the fruit is of the size and shape of a duck's egg, but with longitudinal ribs on the sides; either in tarts or as a preserve, the flavour is described as exquisite. It may be noticed, that, both from the descriptions of intelligent travellers, and from the preserved fruit being sent to Britain, we know that numerous species of exotic fruit-trees exist, which have not yet reached us in a living state; and the introduction of these might form an object of innocent, pleasing, and commendable ambition to enterprising and wealthy horticulturists.

The CHERRY-HOUSE, in its general arrangements, resembles the peach-house, with the exception of the front trellis, the place of which is commonly occupied by a stage for pots of early strawberries or kidney beans. The cherry-trees are trained against the back wall: the house should therefore be narrow, and the roof steep. The operation of forcing generally commences early in January, with a very moderate temperature. Air is admitted freely till the flowers begin to expand, when great caution becomes necessary. When the fruit is setting, the temperature is kept as steadily as possible at 50°: after it is set, abundance of water is applied to the roots and foliage of the trees. When the fruit is colouring, water is almost entirely withheld, and air is now freely admitted. During the whole process of forcing cherries, any excessive heat from the sun's rays must be carefully guarded against, by shading or by admitting of air. The kind of cherry usually preferred for forcing is the Common May-duke. A cherry-house ought to form a part of every large garden establishment; for nothing better distinguishes the tables of the opulent, in March and April, than ripe cherries and strawberries appearing in the dessert at that season of the year.

The FIG-HOUSE scarcely differs in form and management from the Cherry-house, the trees being trained to a back trellis, with the addition, however, of dwarf standard trees in front. At Kew there is a fig-house fifty feet long. Here the second crop is often the most productive. In 1810, we are told the royal tables were supplied with more than 200 baskets of figs, 50 of which were from the first crop, and 150 from the second. It is seldom, however, that a separate house is erected for this fruit. The fig succeeds very well as a dwarf standard between the front flues of a vinery, provided the roof be not too closely covered with the foliage of the vines. Of late, small standard figs have very commonly been grown in large pots, fourteen or fifteen inches in diameter, and placed in any of the forcing houses. In this way considerable crops of fruit have been raised. The *Figue blanche* and the *Marseilles* are the sorts best adapted for forcing.

The ORANGE TRIBE (*Citrus*) are cultivated in Britain, rather as objects of curiosity and beauty, than for the purpose of affording a supply of fruit. Commerce with Portugal, Spain, Italy, and China, has brought this class of fruits within the reach of every one; and the copious importations which annually take place, have no doubt discouraged the cultivation of the plants. A few orange trees are nevertheless to be met with in most collections, and in large and sumptuous gardens, it is not uncommon to meet with glazed houses set specially apart for their reception.

The following brief notices of some of the cultivated species of the genus Citrus are derived principally from Mr G. Don's General System of Botany and Gardening, a work evincing singular accuracy and unwearied research, and from M. Risso's excellent paper in the *Annales du Muséum,* vol. xx.

C. Medica, the Citron, the Cedrate of the Italians, is a small evergreen tree. The fruit is large, of an oval form, and covered with a rough skin or rind, which is charged with a highly fragrant oil. The citron is generally used in confections. It is supposed to be a native of Media, and will scarcely ripen without protection in Britain. Three subvarieties of citron are described by Risso.

C. Limetta, the Sweet Lime. This is rather a tall tree, with diverging branches. The flower is of a fine white colour, composed of five oblong petals. The fruit is globose, with a black nipple-like protuberance at the apex, having a firm rind, and sweet pulp. The colour is pale yellow. It is a native of Asia, but cultivated in Italy. Seven varieties have been described.

C. Limonum, the Lemon. The petioles of the leaves somewhat winged; fruit oblong, with a thin rind adhering closely to the very acid pulp. This, like the preceding, is a native of Asia, but is cultivated in the south of Europe. There are numerous varieties.

C. Aurantium, Sweet Orange. The petioles almost naked; fruit globose, with a thin rind, and sweet pulp. Risso has enumerated nineteen varieties; of which the principal are, the China, the Portugal, and the Maltese.

The last has a blood-coloured pulp, with rich juice, and is now in much request.

C. vulgaris, Seville or Bitter Orange. The petioles winged; fruit globose, with a thin rind, and bitter juice. This sort is employed in making marmalade, and is also used in medicine. Twelve varieties have been described.

C. Decumana, the Shaddock. The petioles broad, with cordate wings; fruit large, weighing from ten to fourteen pounds, with a thick rind. This fruit was carried by Captain Shaddock from China to the British West Indies, where it first acquired the name which it now bears. It is now cultivated not only in the West India Islands, but extensively in South America. Four sorts are enumerated. Of all the Citrus tribe, this has the most beautiful foliage, and it is therefore not improperly selected for filling the back wall of a vinery.

The orangery, in this country, seldom differs in form, even where it is a separate structure, from that of the greenhouse. Most commonly the few orange plants which are kept, are grown in pots or boxes, and occupy a place with other exotics on the greenhouse shelves. At some places the orange trees are planted in conservatories erected for the purpose. In the neighbourhood of Paris, the orangeries are little better than dark sheds, in which the trees are kept protected during the winter months, light and air being given when the weather permits. At Woodhall, in Lanarkshire, they are trained against trellisses, under glass, and in this way produce abundant crops of fine fruit. We have there seen a single plant of the St Michael's orange, twenty-four feet wide and eighteen feet high, clothed with fruit.

Middle-sized plants are frequently imported from the Italian nursery-gardens, and this is the readiest way of procuring large specimens at a cheap rate. The plants are closely packed in boxes, with some grass or moss around the roots. Upon their arrival they are in a withered and dead-like state, and require considerable care and management to recover them from the effects of the voyage. When propagated in this country, they are budded on citron or Seville orange stocks; the former recommended by Miller as preferable. The seeds of the stocks are sown in pots, and the growth of the seedlings is aided, during the first and second summer, by the application of a slight bottom heat in a hot-bed frame. These are usually budded in August. The late Mr Henderson, gardener at Woodhall, used to graft his trees, employing scions formed of the wood of the second year. He also propagated by cuttings, considering this the quickest mode of obtaining plants. We may add, that this most successful cultivator of the orange tribe made it a rule to keep his trees rather cool, and with plenty of air in mild weather, till the fruit was fairly set; after which he found that he could apply more heat without the risk of the fruit failing.

The orange tree prospers in a rich, fresh, and rather strong soil; and in this country it is the practice to mix with it a considerable portion of well rotted dung. When grown in pots or boxes, the plant should be shifted, and the earth partly renewed every spring. In summer, copious waterings are given, and the leaves are syringed once or twice a-week. The heads are kept thin, and the branches which inconveniently cross each other are removed. When planted against trellisses, they are trained in the fan form; and in laying in the shoots, allowance is to be made for the size of the leaves in the different species.

The Pine-apple (*Bromelia Ananas*) is comparatively of recent introduction into Britain. It was nearly unknown to our horticulturists in the beginning of the eighteenth century; for Thoresby, the antiquary, kept a leaf of the pine-apple in his museum as a curiosity. It is now largely and successfully cultivated in all the principal gardens in this country. Its culture requires all the ingenuity, judgment, and watchfulness of the skilful and diligent horticulturist. We shall, therefore, treat of it at considerable length. It derives its name from the general resemblance of its fruit to a large cone of a pine-tree. The fruit is a kind of pulpy strobilus, formed of coadunate berries, and crowned at top with a tuft of fine green pointed leaves. The flavour of the pulp is of the most exquisite kind. The plant is herbaceous, and the fruit-stem, which generally appears in the second or third year, is surrounded with long serrated leaves, resembling those of some species of aloe. The fruit grown in Britain is considered equal in all good qualities, and generally superior in size, to that reared in tropical countries. The *Lond. Hortic. Catalogue* enumerates 56 varieties: of these the following may be deemed most worthy of notice.

The *Queen Pine* is very generally cultivated. Its fruit is of a cylindrical or tankard shape, of a yellowish colour inclining to orange, and sometimes weighs three pounds: it is, at the same time, of excellent flavour. This kind produces with greater certainty than most others, and the fruit may be easily ripened in fifteen or eighteen months, from the planting of the crown or offset. It is, therefore, the most useful of all the pines. A subvariety called *Ripley's Queen* is also excellent.

The *Black Antigua* has leaves armed with large spines; the flowers are purple; the fruit cylindrical, averaging five pounds weight. It should be cut a little before it be quite ripe.

The *Black Jamaica*, or *Old Jamaica*. In this variety the spines on the leaves are small; the flowers purple; the fruit oblong, averaging about four pounds. This is an excellent kind, and is considered the best sort for fruiting during the winter months.

The *New Jamaica* is rather an inferior kind, but is pretty good when ripened in the summer time.

The *Brown-leaved Sugar-loaf* is a capital black variety; and the *Enville* a large, shewy, and useful pine.

The *St Vincent's*, or, as it is sometimes called, the *Green Olive*, has middle-sized spines, purple flowers, and pyramidal fruit, which average about two pounds and a half. It succeeds well to come in as a winter fruit.

The *White Providence* has small spines, dark purple flowers, and oblong fruit of a large size, averaging, when well grown, seven pounds weight, and sometimes exceeding twelve pounds. The colour of the fruit is at first brownish-grey, but at ripening it becomes of a pale yellow. The pulp is yellow, melting, and abounds with quick lively juice, but is not equal in flavour to some of the other kinds.

The *Trinidad* is remarkable for the great size of its fruit, which are said to attain sometimes to the weight of twenty-six pounds. Its average is stated in the *Hort. Cat.* to be twelve pounds. The spines are middle-sized, the flowers lilac, and the fruit pyramidal. Apart from its magnitude, it is, like the preceding, only a secondary fruit.

The following may also be named as first-rate sorts: Bagot's Seedling, Russian Globe, Green King with smooth leaves, Striped Queen, Sierra Leone, Brown Sugar-loaf, and Orange Sugar-loaf. And three or four more, though of inferior quality, may be noticed for their beauty, or curiosity, viz. the Blood-red, Otaheite, Scarlet, Welbeck Seedling, and the Havannah, the fruit of which last keeps long, and has sometimes been imported into this country from Cuba.

Structures for growing Pine-apples. The ananas plant has generally been found to require cultivation for two or three years before it perfects its fruit: its culture has, in consequence, been divided into three periods,—propagation, successional preparation, and fruiting; and each of these periods has its corresponding structure, viz. the nursing-pit, the succession-house or pit, and the fruiting-house.

The *nursing-pit* has occasionally assumed a great variety of forms, respecting which, however, it is not necessary to go into minute detail. For summer use, a large glazed frame, placed upon a hot-bed of stable litter and tanners' bark, is perhaps the best hitherto devised. The Alderston Melon-pit, and Atkinson's Melon-pit, described under the head Melonry, are likewise very suitable for this purpose. In winter, it is desirable to have the assistance of fire heat, either from flues, or, what is better, from hot water; though this fire heat is not indispensable.

The *succession-pit* performs the same functions as the nursing-pit, but at a more advanced stage of the growth of the plant, and consequently requires an increase of size. With this difference, Atkinson's Melon-pit does very well for summer use. In colder seasons, we should prefer a pit similar to that represented Plate CCXCII, figs. 2 and 3, in which a hot-water apparatus on the siphon principle is employed. The plants are plunged in *a* (fig. 2), being a bed of sand or fine gravel; *b* is the boiler; *c* pipes for supplying the bottom heat; *d* exposed pipes for warming the included air. If the common bark-bed is preferred, the pipes *c* may be omitted. This pit may be fifty feet long, and seven wide. The sashes are raised from without, as in the common hot-bed. This plan is from the pencil of Mr Charles H. J. Smith, a young but very promising garden-architect, of whose assistance the writer of this article has had much satisfaction in availing himself in the designing of the plates. Mr Smith also proposes another form of a succession pit, exhibited in Plate CCXCII, fig. 11, entirely heated by hot-water. The surface heat is supplied by pipes in front; the bottom heat is kept up by small pipes from the boiler, passing through cisterns of water extending the whole length of the pit. In this case it would be necessary to apply the heat only during the day. The old succession-house, or that generally in use till within the last fifteen years, does not differ materially from the common pine-stove; but, owing to its great waste of heat, it either is or ought to be entirely laid aside.

In the *fruiting-house*, more room, greater height, and a more powerful temperature, are requisite; and to attain these objects, many varieties of structure have been devised: we shall notice those only which are most worthy of attention. Fig. 4, Plate CCXCII. is a section of Baldwin's Fruiting-pit. The roof is unequally ridged, the north or shorter side being slated and furnished with ventilators, to admit air. The sashes are immovable, and the laps of the panes are closely puttied. There is a path within, and a single turn of a flue behind. We should prefer the form exhibited by fig. 5. of the same plate, in which there are also ventilators *a a*, and a hot-water apparatus surrounding the whole pit. The dimensions of this may be fifty feet long, and nine feet wide; the glass being two feet and a half from the curb of the bark-pit in front, and five feet behind. Fig. 6. is a section of a pine-pit with a curvilinear roof, in which the astragals are parallel. A segment of an elliptical arch somewhat less than a quadrant, the origin of the curve being on the front wall, seems better adapted for a pit than any portion of a circle. This pit is supposed to be heated by a small steam-pipe passing through a large iron tank or cistern *a*, filled with water, on the same principle as exhibited in Plate CCXC, fig. 13. A section of the old-fashioned pine-stove is given in Plate CCXCII, fig. 7. This is a lofty structure, in the vinery form, with front sashes. It used to be forty or fifty feet long, and twelve or fourteen feet broad, and was commanded by two flues. In addition to the pine plants in the pit, the roof is also partly covered with vines, a practice justly condemned by Nicol. We are also disposed to agree with that experienced writer regarding the disuse of the pine-stove itself. Besides other grievous faults, a single house affords too little room; and it is a matter of experience, that where the stock of pine plants is not extensive, certain and abundant crops of fruit cannot be expected. Instead, therefore, of a succession and fruiting-house of the old form, with two fires each, it would be better to have four pits with single fires. There might be two succession-pits of the form of fig. 2. or fig. 11, Plate CCXCII, and two fruiting-pits similar to fig. 5. or fig. 6. These would contain a much greater number of plants than two pine-stoves, would be little more expensive in erection, and, as the number of fires is the same, would not consume much more fuel.

Bottom Heat. As a substitute for the warmth absorbed by the earth, from the powerful rays of the sun in tropical countries, the pots of pine-plants are generally plunged in a bed of tanners' bark, decaying leaves, or other fermenting substances. Tanners' bark is most commonly used. Speechly and Nicol prefer leaves shed by hard-wood trees in autumn. Others form the under and greater part of the bed with stable-litter. Whatever substance is employed, it should not be put into the bed until the first violent heat of fermentation has passed; or if circumstances impose a necessity of using it in a recent state, it should be largely mixed with old materials of the same kind. A layer of exhausted bark, ten or twelve inches thick, should be laid on the surface of the bed. In pine stoves, the curb of the bark-pit is usually elevated about three feet above the common level of the house, and has a gentle slope towards the front; in pine-pits, however, it approaches more closely to the glass. The bark is commonly five or six feet deep; but it may be questioned whether this depth is not excessive and unnecessary. A bed about three and a half feet deep would probably be more convenient, and afford a heat sufficient both in intensity and duration for any useful purpose.

We have already shewn how a system of tubes transmitting steam or hot-water may be made available to the production of bottom heat. There is another method worthy of at least a cursory notice, which is all that we can afford it. Its invention is due to Mr M'Murtrie, and the apparatus is described at length in the *Lond. Hort. Trans.* vol. vi. His contrivance will be understood by an inspection of his pine-pit, of which a section and plan are given in Plate CCXCII. figs. 8 and 9. A shallow bark bed, about two feet deep, rests upon an arched chamber of single brick. 1 is the fire-place; 2 a fire-flue running along the whole length of the chamber 4, which is also kept full of steam by means of the boiler and pipe 3; the apertures 5 admit steam and heat into the air of the pit, and of these there is one, both in back and front, under each sash, capable of being stopped at pleasure. The waste-pipe 6 allows the steam to escape, when the apertures marked 5 are shut. By the return of the flue 2, the atmosphere of the house is heated; and by the joint action of the inclosed part of the flue, and of the steam in the chamber, an abundant and salubrious bottom heat is easily maintained.

The proper management of bottom heat is a matter of some difficulty, and in this there have been more failures than in any other part of the pine-apple culture. The heat arising from violent fermentation, is greater than the tender roots can bear, and if all watchfulness be not employed, the labour of many months may be blasted in a single day. Mr Knight has discarded bottom heat altogether; but he has not succeeded in convincing others that pine-apples can be grown equally well without it. Bottom heat is, however, almost universally kept too high. Perhaps the upper limit of its temperature may be fixed at blood-heat, or at most 100°, while the under or winter limit may be brought down to 70° or 75°. Gardeners are accustomed to judge of the heat of the bed, by means of long sticks pushed into it; these are occasionally drawn out and felt by the hand, and a rough guess at the temperature is thus obtained. A far preferable method is to employ a slow thermometer slightly cased in wire.

Forcing Garden.

Soil. Various nice and minute directions have been given respecting composts for ananas plants. Any compost, however, will be found suitable, which is at once rich, fresh, and simple. Perhaps a mixture of the top-spit, including the turf, of an old pasture, and about a half of good, well-rotted dung, combines these qualities as completely as possible. When it is necessary to lighten these materials, a compost of decayed leaves, and a little sand, may be added. It is of importance that the compost, whatever it may be, should be prepared a considerable time beforehand, and frequently turned over. It should be broken with the spade, but not screened; and when used, it should not be too moist. Pine-apple plants are found to shew fruit more readily in a rich light soil, than in strong loam, but do not produce large fruit. In selecting his compost, the cultivator must make his selection between these advantages. At all events the soil must be rich; it can scarcely be too rich. "The pine," says an intelligent writer in the Gardener's Magazine, vol. ix. "is a gross feeder, and will thrive in vegetable manure, however rich and fresh." Liquid manures have been applied; but these, however useful when recent, prove deleterious in a fermented state.

Propagation. The ananas is propagated by planting the crowns or tufts which grow on the fruit, or the suckers which appear at the base of the stem. These, when removed from the fruit or the stem, are laid aside for a few days, till the scar at the place of separation have dried or healed, a precaution to prevent their rotting; after which they are potted immediately. Sometimes late in the season, they are merely thrust into exhausted tan, without pots, where they remain till the following spring. In general the offsets should be as large as possible. Speechly did not break off his suckers before they were twelve or fourteen inches long, and he reserved only the largest crowns. These large suckers and crowns grow with greater rapidity, and come sooner into fruit, than those of smaller size: and in this, in truth, consists the principal secret of what has been called the short method of culture, by which fruit is obtained in a much briefer space of time than usual. The soil employed in propagation is rather lighter than that afterwards applied. The pots may be from three to six inches in diameter, and, to promote draining, should contain at bottom a layer of shivers or clean gravel. For some time the plants are shaded from the rays of the sun, and in about eight or ten days they receive a little water. As already stated, the older and more common routine of pine-apple culture embraces a period of three years; but recent improvements have reduced these to two years, or even to eighteen months. This has given rise to two modes of preparatory management, which we shall notice separately, premising that the treatment in the fruiting-house is the same in both.

Triennial Course. The plants which were potted in autumn, are kept in the nursing-pit during winter, with a mild temperature, a slight bottom heat, and a sparing allowance of water. About the beginning of April they are transferred into larger pots, and are commonly shifted into hot-beds or pits heated with stable dung, in which they are found to prosper exceedingly. Air is given every day, and is copiously admitted, as soon as the sun's rays have acquired considerable power. During summer the average morning temperature may be from 70° to 75° Fahrenheit, but in sunshine it may be allowed to rise to 85°, 90°, or even more. The heat is maintained by adding occasional linings of stable litter, and, when it is exhausted, the plants are transferred into other beds or pits, more recently made up, and in which fermentation is going on. In flued nursing-pits the management is precisely the same. The bottom heat is aided by fresh additions of tan. As nothing is to be dreaded from damp where there is a command of fire-heat, more copious waterings may be given, and the plants may be syringed over head, or slightly steamed, by throwing water on the flues. It is not very common to shift the plants in the nursery during summer; but it is a good rule to have recourse to that operation as often as the roots begin to mat on the sides of the pot. Before the end of autumn, the young plants become vigorous. The lower part of the stalk should then be thick, the centre or funnel formed by the leaves should be upright, open, and rather short, and the leaves themselves not long nor very numerous, but broad, stiff, succulent, and free from contortion and deformity. Towards the end of autumn, the plants are taken into the succession-pit, which, in fact, is only a nursing-pit on a large scale. The temperature for winter should be about 60°. About the middle of March, they are shifted into pots nine or ten inches in diameter. At this period, it is not uncommon, in compliance with the recommendation of Abercrombie and the other older authorities, to cut away the whole of the roots, and to re-pot the plant somewhat in the capacity of a sucker. The reasons alleged for this extraordinary practice are, that the pine-apple plant is continually pushing out roots at the surface, while those below are rapidly dying; that the soil, in the course of three years, becomes completely exhausted; and lastly, that this treatment prevents premature starting in the course of the second year. This last reason is very questionable, and it assumes that ananas plants *must* be treated for three years before they produce fruit. There is some force in the other reasons, but they do not prove the absolute necessity of the practice. Roots may be pruned without being removed altogether. The earth may be shaken almost entirely away, and replaced by fresh compost, at the expense of only a few fibres. Again, if, at every shifting, a small portion of the earth be taken from below, as florists treat auriculas in pots, at the end of two years scarcely any portion of the original soil will remain. The grand objection to the operation is, the great and unnecessary check to vegetation, and the consequent stuntedness of habit, which, in succulent plants of such an age, is scarcely remediable. That it is possible to grow ananas without cutting away the roots, is consistent with our own observation, and is borne out by the testimony and practice of Griffin, Appleby, and other distinguished cultivators. When the roots are removed, the plants must be shaded for some time, and be watered sparingly, till they begin to grow freely. The summer temperature should be comparatively warm, the range being from 65° to 70° of fire-heat, or during night, and from 70° to 85° solar heat. Abundance of air is admitted, and the plants are set widely, that they may have room to swell below, and become stout and bushy.

Biennial Course. The method of culture which we have denominated the biennial course, was first brought into notice by Abercrombie, and more recently has been strenuously recommended by Baldwin. Its chief feature is the acceleration of the growth of the plants by the application of higher temperatures than it was formerly supposed they could bear. They are, in fact, made to attain the growth of two summers in one.

About the beginning of March, the most forward of the plants potted over winter, or the suckers kept in tan, are taken out, the earth or tan shaken away, and the roots shortened. They are then put into pots about five inches in diameter, which are plunged into frames or pits heated with tan or stable litter. They are shaded as usual, and after they begin to grow, receive moderate waterings. When the roots appear around the balls of soil, which will be about the middle of June, the plants are again shifted into larger pots, from six to seven inches in diameter, and, if the heat be declining, are removed into other pits or beds. In the beginning of August they are transferred into larger pots, in which, unless they are intended for early spring forcing, they stand during the winter; and in February they are finally shifted into pots twelve or fourteen inches in diameter. For spring forcing, the last shifting takes place in October, and the pots may be two inches narrower. At every shifting the ball of earth is preserved entire. From March the temperature is gradually increased; little air is admitted, even in strong sunshine, and a lively bottom heat is kept up by means of repeated linings. When there is danger of burning the roots, the pots are partially drawn up, or even set upon the surface of the tan. The following table will give an idea of the temperature (Fahrenheit's thermometer) and its progressive increase:

	During Night.	During Day.
March......	60° to 70°	70° to 80°
April........	70 — 75	80 — 85
May.........	75 — 80	90 — 100
June........	80 — 85	100 — 120

After the beginning of July, the heat is allowed to decline by degrees, until it arrive at the winter temperature of 60°. It is to be understood, however, that these temperatures regard only stable dung or tan heat; and that too applied to crowns, as the larger suckers seldom require more than 100°. Where fire-heat is used, and it should always be through the medium of hot-water, the nocturnal temperature should only approach towards 80°; and there should be some expedient for the *slow* immission of steam into the atmosphere of the pit. During the whole summer care is employed to prevent the plants from being *drawn*, and for this purpose they are allowed much space, and are placed as near the glass as possible. In August and September abundance of air, and more copious supplies of water, are given. In winter the chief care is to preserve the roots from damping off, and for this reason, though it is not the common practice, we should prefer winter pits having at least the command of fire-heat.

This mode of *driving*, as it has been significantly called, is applicable only to the varieties called the Queen, and Ripley's New Queen. The large growing sorts require a longer period. For this reason it is desirable that both courses of culture should be carried on at one time. The large varieties might be consigned to the triennial course, while the vacancies in either might be made up from the other. That this is practicable, at least in gardens where there are two fruiting houses, may be seen from the tabular compendium of culture given below.

Fruiting-House.—About the beginning of August, the plants, now two years old, are shifted for the last time. The pots are from twelve to fourteen inches in diameter, and the balls are preserved entire. About eight or ten days previously, the bark-pit of the fruiting-house has been cleared out, the old tan screened, if necessary, and fresh material supplied. The pots are then plunged into the bark as deeply as can be done with safety, and the plants are so treated as to keep them in a growing state during the whole of autumn. In winter, the nocturnal temperature is kept at 60°; but towards the end of January it is gradually raised to 70°. This rise, however, should follow, and not precede or be a cause of, the vernal growth of the plants. About the middle of February, the second fruiting-house may be prepared, for the reception of the plants in the biennial succession pit. These are existing in a mild temperature, and start during the general progress of the season.

That period at which pine-apple plants first shew their fruit-stalks, or, as it is technically termed, *start*, is the most critical in their whole culture. It is generally desirable that this should happen at a certain age, and at a particular season; but these are circumstances over which the cultivator can scarcely be said to have a direct control, and accordingly, while the most successful can hardly deem themselves beyond the reach of failure, the less skilful are almost sure to err. We are not aware that the *rationale* of starting has been investigated on the principles of vegetable physiology; and it is certain that the most absurd practices have been resorted to, in order to force the plants into fruit. We pretend not to give a theory: but a few practical remarks may be of advantage. It is evident, then, that the plant must be of a certain age, or at least of a certain magnitude, before it will start freely or to good purpose. Suckers of the first year are wholly taken up with the production of roots and foliage; and if any of them happen to start, they exhibit little more than a tuft of leaves where the fruit should be. In the second year a Queen pine is capable of producing a perfect fruit; and in the third year the New Providence and other large varieties arrive at puberty. The solid part of the stem is then observed to have increased in bulk, and to have ascended considerably above the soil. It is of more practical importance, however, to remark, that the fruit-stalks do not appear until the pot is filled with roots. Apparent exceptions there may be to this principle, but in every case where it does not hold good, the plant will be found to be diseased, or the roots to have been violently destroyed. The grower should therefore take care that the roots shall have nearly occupied all the new soil before the end of autumn, and that in the course of the winter the tender fibres be not exsiccated by drought, or rotted by excessive moisture. Again, it is probable that at starting there is a peculiar check in the growth of the plant, which causes it to divert the sap from the formation of leaves, and, like most other vegetables in straitened circumstances, to provide the means of reproduction, by throwing out flower-buds. This diversion of the sap is influenced by the quantity of vigorous fibres, for it is observed that when, from some accident, plants not well furnished in this respect, do shew fruit, they bestow the greater part of the sap upon the leaves. Further, it is not a mere suspension of vegetation, otherwise fruit would be produced by every plant which has had the roots cut from it in the manner noticed above. Lastly, it is probable that the proper check consists in a transition from growth, however slight, to a temporary suspension of vegetation, which again is followed by a copious flow of the sap, circumstances which, as might be easily shewn, occur both in the winter and summer starting. If these imperfect observations be correct, it follows that starting is a natural process, requiring certain conditions in the state of the plant, and therefore not to be forced by violent treatment, or any sudden changes in temperature and watering.

After the plants have shewn fruit, they are never shifted; but the surface soil may be removed, and replaced by a little fresh and rich compost. Water is supplied from time to time as necessity requires; but it is impossible to give any definite rule on this subject. The observant gardener will soon, from experience, discover the proper measure. Water should never be given in a colder state than the average temperature of the house; when, therefore, there is no tank within the house, the watering-pots should be filled, and left in the house for some time before the water be applied. Fire-heat is kept up either continuously or at intervals, during the greater part of the season. It should always be moderate, never exceeding, by itself, 70°. During sunshine, the temperature may range from 70° to 100°. The greater proportion there is of the latter the better. Whilst the fruit is swelling, care must be taken to carry on the growth of the plant with equability and moderation. Violent checks are pernicious: they debilitate the stalk, and cause a stringiness in the fruit. As the fruit approaches maturity, water is gradually withheld, lest the flavour should be injured. Pine-apples should be cut a short time before they attain complete maturity. The

Forcing Garden.

larger varieties will keep only a day or two; the smaller varieties a week or more.

The following tabular compendium is from Abercrombie, altered, however, in some of its details, to suit the idea of two crops a-year. To execute this plan, two fruiting-houses or pits, and one succession-pit, would be required, together with a variety of hot-beds, or pits for the nursing department. It is necessary to premise, that crowns and suckers are usually potted soon after they are taken off, and that August 15. may be considered the date at which the whole operations of potting should be finished. When there is only a biennial course, it commences from about February 14.

COMPENDIUM OF THE CULTURE OF ANANAS.

TRIENNIAL COURSE.	BIENNIAL COURSE.
Nursing Pit.	*Nursing Pit.*
1833. Aug. 15. Crowns and suckers of the New Providence and other large varieties planted: also small crowns and suckers of the Queen pine. 1834. Feb. 14. Small off-sets of the Queen pine dibbled into the tan. April 1. The above potted, or re-potted; the balls of earth preserved entire. July, Aug. } The intermediate shifting: time determined by expediency.	1833. Aug. 15. Large crowns and suckers of the Queen pine planted. 1834. Feb. 14. Large off-sets of the Queen pine dibbled into the tan. Mar. 15. The above potted, or re-potted; the earth or tan is shaken away, and the roots pruned: the pots transferred into hot-beds or pits. June 15. First intermediate shifting. Aug. 1. Second intermediate shifting.
Succession Pit.	*Succession Pit.*
1835. Mar. 1. The plants from the nursing house are shifted into larger pots: the greater part of the earth is renewed, and the roots pruned. June 1. Second intermediate shifting.	1834. Oct. 1. Plants introduced from the nursing pit; but not shifted unless intended for early spring forcing.
Fruiting House.	*Fruiting House.*
1835. Aug. 15. Between this period and September 15, the plants, after having been shifted into full-sized pots, are introduced from the succession-pit. 1836. March. The surface of the pots are top-dressed. 1836. June, Aug. } Fruit ripens, and the course concludes.	1835. Feb. 15. Plants shifted for the last time, and introduced from the succession-pit. 1835. Sept., Dec. } Fruit ripens, and the course concludes.

The MELONRY—a department deriving its name from the melon, the principal plant cultivated in it—is an important appendage of the forcing garden. After noticing some of the most necessary apparatus employed in it, we shall treat of the melon, cucumber, &c., and their culture respectively.

The *common hot-bed frame* is most usually employed, and is so well known, as scarcely to require description. It is a rectangular box, with sliding sashes, which are single, in pairs, or in threes. The length of the sash is five or six feet, and its breadth about three feet and a half. The back of the frame is about double the height of the front, and the slope is set towards the south. When used, it is placed on a bed of fermenting stable litter, from three to six feet in thickness, according to the purpose to which it is to be applied, or the severity of the season.

The Alderston Melon Pit, of which fig. 6, Plate CCXCIII. is a section, is partly above and partly below ground. The front and back walls *a*, *a*, are of brick, supported on piers or stone pillars: *b*, *b*, are spaces inclosed within outer walls, and covered with boards to contain linings, which communicate, without any object intervening, with the fermenting substances in the interior of the pit. These spaces may be two feet wide: the interior pit should seldom be more than six feet in breadth. A principal quality of this structure is its neatness and cleanliness. *Caled. Hortic. Mem.* vol. ii. p. 217.

West's Melon and Cucumber Pit is also built of brick. It has, Plate CCXCIII. fig. 7, a chamber *a* to contain dung; *b* a square opening by which the dung is introduced; *c* rafters of wood or cast iron, sustaining the interior soil; *d*, *d*, openings to permit the ascent of steam. The walls are nine inches thick, and the pit may be seven feet wide inside measure. *Lond. Hort. Trans.* vol. iv. p. 220.

Atkinson's Melon Pit, Plate CCXCII. fig. 10, is a brick structure. The back wall *a* and the end walls are four inches thick, built in the pigeon-hole fashion, that is, with square interstices between the bricks. The front wall *b* is double: the interior portion is brick in bed, the exterior brick on edge, with piers under each rafter. The included space communicates with the inside of the bed *c*. The pit *d* is filled with fermenting litter or tanners' bark: *e*, *e*, are spaces for linings. This pit, according to the experience of the Horticultural Society of London, has been found "far superior to any other yet constructed." *Trans.* vol. vi. p. 373. The whole is sometimes formed of wood, or sometimes only the part above ground.

Besides these, pits constructed on the principles exhibited in Plate CCXCII. figs. 2 and 11, may also be employed.

The extent of the melonry must depend upon the size of the garden, and the amount of the demand. Where there is a large family, and especially where pine-apples are cultivated (to the forwarding of which some portion of the melonry may frequently be auxiliary), sixty or seventy sashes may be considered as a moderate complement.

The MELON (*Cucumis Melo*) has long been cultivated in Britain, but the period of its introduction and its native country are not well ascertained. The plant is a tender annual, requiring considerable care and skill to rear it in perfection; but it repays the labours of the horticulturist by affording a large, and to most persons a highly palatable fruit. The varieties are numerous, and, from their tendency to sport or vary, are rather fugitive in their duration. Many of the old favourites have disappeared, and those at present in vogue will doubtless take the same course, or will at least assume new forms, while they retain their old names. In these circumstances, it is deemed unnecessary to enter into minute description, or to do more than give a list of the sorts at present deserving of cultivation. It may be premised, that they all belong to the species usually called the Musk-Melon. The Water melon

(*Cucurbita Citrullus*) appertains to another genus, and is seldom reared in this country except as a curiosity.

- Des Carmes,
- Green-fleshed Egyptian.
- Green-fleshed Italian,
- Daree Persian,
- Green Hoosainee Persian,
- Keiseng Persian,
- Sweet Melon of Ispahan.

It is important that none but such seeds as have been procured from approved genuine specimens of the several sorts should be sown. In general, the fresher or more recent that garden seeds are, the better; but the case is different with the melon. Here it is desirable that the seeds should have been kept in a dry state for some years: it is found that plants produced from recent seeds push too vigorously, sending their shoots to a great length before they shew a single fruit; while those from old seeds are less luxuriant in growth, but more fruitful.

The melon succeeds best in a strong, rich soil. A compost, formed of two-thirds of rotted turf, and one-third of old cow-dung, will be found very suitable. This should be prepared for a year or two before it be employed in the melon frame.

There are generally several, perhaps three, successive crops of melons raised in large gardens. It is seldom expedient to sow before the middle or end of January, and sometimes it is soon enough a month later. A seed-bed capable of receiving a frame with a single sash is previously prepared. This bed, composed of fermenting stable litter, should be of considerable thickness, perhaps about five feet. Immediately upon its formation, the frame and sash are placed on it, and they are kept close till the heat begin to rise, when the hot vapour is permitted to escape. Three or four days after the bed has been formed, it is covered over to the depth of three inches with earth prepared beforehand. Rich, light, dry earth, is best adapted for this purpose; and that it may be dry enough, it is proper to use such as may have been protected from rain during winter. A few small flower-pots are filled with the same earth, and kept in the hot-bed, that the soil in them may acquire a suitable temperature. The seeds are then sown in the flower-pots, and covered half an inch deep; after which the pots are plunged a little way into the earth of the bed.

When hot vapour rises copiously, fresh air is admitted by raising the sash a little. The frame is covered every evening by sunset with mats, and is again exposed in the morning about nine o'clock, sooner or later according to the state of the weather. A single mat is sufficient at first, as the heat in the bed is generally strong. In two or three days after the seed has been sown, the plants appear, when the glasses are raised a little, to admit fresh air, and permit the escape of vapour. Unless this be done, the plants are apt either to damp off or become yellow and sickly. To guard against the casualties of the season, and the chance of miscarriage, it is proper to make two other sowings at short intervals, so that, if any accident befall the first plants, the others may supply their place. Two or three days after the plants have come up, they are transplanted into other small pots, only two or three being put in each pot. If the earth be very dry, it is now moistened with a little tepid water. The pots are then plunged into the earth, and much care and watchfulness are employed to prevent the roots from being scorched. When the transplanted seedlings begin to grow, they are watered occasionally in the warmest part of the day. As the heat of the hot-bed declines, it is supported by linings, applied from time to time, around its outer surface. The lining should not exceed fifteen or eighteen inches in thickness, and should rise above the level of the bed, upon the sides of the frame.

About a month after the seeds have been sown, hot-beds or pits are prepared for the reception of the young plants. For the first crop, it is generally found that hot-beds are preferable. These are formed about three feet and a half thick, and of such extent as to receive several frames of two or three lights each. The same precautions with respect to vapour, and other matters connected with the fermentation, are observed as in the seed-bed. When the violence of the heat has begun to subside, the surface of the bed is covered, to the depth of two inches, with dry, light earth; and under the centre of each sash, a conical heap of the same soil is raised to the height of ten inches. By the following day, the earth generally acquires a sufficient warmth, and the bed is ready for the reception of the plants. The pots containing the young plants should be well watered the day previous to their being *ridged out*, to make the ball adhere together, and come out of the pot entire. After the tops of the hillocks of earth have been flattened a little, in the centre of each a hole is made capable of containing one of the balls of earth which is to be turned out of the pots. Some of the pots containing the strongest plants are selected, and the young melon-plants are plunged out, with balls entire, into the ridges or hillocks already mentioned. After this operation has been performed, they receive a gentle watering. The sashes are replaced, and for some time, unless the vapour be strong, little air is given. Care is taken to prevent the tender fibres from being scorched. When the roots begin to show themselves through the surface of the hillocks, a quantity of fresh earth is applied all around them, and in a week or fortnight after, the whole surface of the bed is covered nearly as high as the top of the hills.

When the plants have got two or three rough leaves, the top of the stalklet, which now begins to elongate, is pinched off, and from the axillæ of the leaves lateral shoots are soon shot forth. These are fastened down with pegs, and are so disposed as regularly to cover the surface of the bed. These laterals will sometimes show flowers at the second or third joints; if they do not, they are topped in their turn, and afford laterals, which seldom fail to be fruitful. As these runners advance, they are trained along the surface, and all weak useless shoots are removed. This should be done frequently, as it is found injurious to cut out a great quantity of shoots and foliage at one time. No plant, as has been shown by Mr Knight (*Hortic. Trans.* vol. i.), is more beholden to its leaves, both as respects health and flavour of fruit, than the melon.

It is seldom proper to leave more than one fruit on each shoot, and in the large kinds perhaps not more than four or five fruit should be left on one plant. When the fruit begins to swell, a slate or piece of tile is laid under each, to separate it from the damp soil of the bed. During the process of growth, the fruit is usually turned about once a-week, to expose all sides to the rays of the sun; but, in turning, care must be taken not to twist the foot-stalk, as this would destroy the fruit altogether. At this period water is given with moderation, and abundance of air is admitted. The fruit should be gathered before it be quite ripe. Its approaching maturity is known by the appearance of a number of cracks near the footstalk, and by the emission of a rich odour. It is cut in the morning, and is kept in a cool place till served up; if this precaution be not attended to, there will be a considerable deficiency of flavour.

The average heat required for the successful growth of melons is about 70° Fahrenheit. In the common hot-bed, this is maintained by defending the bed during the night, and by applying linings from time to time. In pits heated by hot-water circulation, this is easily effected at any season; and were it not that the included air is apt to become too dry, especially in winter, when much heat is required, such pits would doubtless supersede the hot-bed frame altogether. At present the old methods, partly it may be from custom,

Forcing Garden.

are still principally employed. It is unnecessary to give minute directions respecting the management of melons in pits; as, in these, the mode of procedure recommended for hot-beds, with some trifling variations, will also prove successful.

The Cucumber (*Cucumis sativus*), like the melon, is a tender annual, requiring the assistance of artificial heat. It properly belongs to the class of culinary vegetables, being used in salads and pickles, and has long been cultivated in this country. Its culture, however, requires the closest attention of the gardener. The sorts commonly grown are,

The Early Frame,
Long Prickly,
Short Prickly,
Green Turkey,
White Turkey,
White Spined.

Of these, the long and short prickly are well suited for ridges in the open air.

The culture of early cucumbers so much resembles that of the melon, that it would be useless repetition to enter into minute details. The cucumber, indeed, is somewhat the hardier, and therefore in summer requires less heat; but in every other respect the management of the plants is precisely the same. The first crop of cucumbers is generally sown in the end of December, or the beginning of January; a second in March, and a third in June. In summer, cucumber plants, after they have been fairly established, require scarcely any other attention than to thin them out occasionally, and to supply them with water.

Cucumbers, particularly the prickly sorts, are often raised in the warmer months under hand glasses. A cavity is made in a border in front of a wall or other warm place, and is filled with hot dung. This dung is covered with earth, and two or three plants are put into it, and sheltered with a hand-glass. They are watered and dressed from time to time; and by this means a sufficient supply of small cucumbers, or *girkens*, is obtained for pickling.

In the southern counties of England, pickling cucumbers are easily raised without any artificial heat, being sown in drills in the open ground. The earth is made fine and level, and shallow circular hollows are formed with the hand, a foot wide, and half an inch deep in the middle. The distance between each hollow is three feet and a half, and the distance between the rows five or six feet. Eight or ten seeds are deposited in each cavity. This is done in the beginning of June. When the plants appear, they are thinned out to three or four, the weakest or least healthy being rejected. They are watered occasionally, according to the state of the weather. The cucumbers are gathered chiefly from the middle to the end of August. Vast quantities of these open ground girkens are taken to the London market. The village of Sandy, in Bedfordshire, has been known to furnish 10,000 bushels of drilled cucumbers in one week.

Gourds, species or varieties of the species of the genus *Cucurbita*, may be grown like drilled cucumbers, or trained against walls or on pales. Though occasionally used as esculents, they are regarded chiefly as curiosities. The *Succada*, or vegetable marrow, is a very useful sort, and in request for the table, being eaten stewed with sauce or mashed like turnips. It may be raised in an exhausted melon-frame or pit; or it may be sown under a hand-glass, and afterwards transplanted into a good aspect, and trained against a wall or trellis.

The Mushroom (*Agaricus campestris*), though not properly an inmate of the melonry, may appropriately enough, from the nature of its culture, be taken along with the plants grown in this department of the garden. It is a well-known fungus, a general favourite, and esteemed a delicacy during winter and the spring months.

Mushrooms used to be grown in ridges or prepared beds, in sheds, or covered with litter in the open air. Of late years, the Russian form of the mushroom-house has been introduced into Britain by Mr Isaac Oldacre, and is now in very general use. Its arrangement may be seen by inspecting the back part of the vinery fig. 3, Plate CCXCI. Two tiers of boxes, three in each tier, and supported by a strong frame-work, are constructed round the whole house, with the exception of the spaces occupied by a door and two windows. The boxes may be from two feet and a half to three feet and a half broad, and about a foot deep. The house is supposed to be heated by hot-water circulation. In the centre *d* is a narrow pit, by which the house may be worked by means of fermenting litter instead of the hot-water, or in which rhubarb stalks, &c. may be forced. The windows are furnished with shutters to regulate the admission of light, and are moveable, to permit the ingress of air.

Mushrooms are propagated from what is technically called *spawn*, which is a collection of vegetable threads pervading dried dung or other similar substance, having the smell of mushrooms, and apparently the fungus in its undeveloped state. It may be obtained from old pastures, decayed mushroom beds, or purchased from nurserymen in the form of *bricks* charged with spawn. When once obtained, it may, like leaven, be indefinitely preserved. If not otherwise procured, it may be produced, or in a manner generated, by placing quantities of horse-dung and rich earth in alternate layers, and covering the whole with straw, to exclude the rain and air. Mushroom spawn commonly appears in the heap in about two months after the dung and earth have been laid together. The droppings of stall-fed horses, or of such as have been kept on dry food, are found preferable for this purpose.

The old method of growing mushrooms has been referred to above; and, as it has some conveniences, particularly for those who have not extensive apparatus, it may be proper to give some account of it. The beds are formed of horse-droppings which have been laid out for some time without having fermented, and may be made two or three feet broad, and of any length. A layer of dung about eight or ten inches thick is first deposited, and covered with light dryish earth to the depth of two or three inches; then another layer of dung of the same thickness, covered like the former; and lastly a third layer, with its covering. The whole should grow narrower as it advances in height. When the bed is finished, it is covered with straw to protect it from rain, and from the parching influences of the sun and wind. In ten days the bed will be ready for planting or spawning. Pieces of spawn bricks are inserted in the sloping sides of the bed, about four or five inches asunder. A layer of fine earth is then placed over the bed, and the whole is covered with a thick coat of straw. When the weather is temperate, mushrooms will appear in about a month after the bed has been made; but at other times, a much longer period may elapse. The principal things to be attended to are to preserve a moderate state of moisture, and a proper degree of warmth; and the treatment at different seasons must vary accordingly.

Of the many other methods of raising mushrooms, Mr Oldacre's, already referred to, may deserve to be particularised. In forming the compost, he procures fresh short dung from a stable, or from the path of a horse-mill. To this is added about a fifth part of sheep-droppings, or of the cleanings of a cowhouse, or of a mixture of both. The whole ingredients are thoroughly mixed and incorporated. A stratum of the prepared mixture, about three inches thick, being deposited in the boxes already described, is beat together with a flat wooden mallet. Another layer is added, and beat as before; and this is repeated till the beds be rather more than half a foot thick, and very compact. The boxes are then placed in the mushroom-house, or any out-house where a slightly increased temperature can be commanded. A degree of fermentation generally takes place; but if heat be not soon perceptible, another layer must still be added, till sufficient action be excited. When the beds are milk-warm, or between 80° and 90° Fahrenheit, some holes are dibbled in the mass to receive the spawn. The holes are left open for some time; and when the heat is on the decline, but before it be quite gone, a piece of spawn-brick is thrust into each opening, and the holes are closed with a little compost. A week afterwards the boxes are covered with a smooth coating, an inch and half thick, of rich mould mixed with about a fifth part of horse-droppings. The apartment is now kept as nearly and equably at 55° Fahrenheit as circumstances will allow. When the boxes become dry, a little soft water may be sprinkled over them, but sparingly and with circumspection. The more that free air can be admitted, the flavour of the mushrooms is the better; but the exclusion of frost is indispensable. If a number of boxes have been prepared at first, a few only at a time may be covered with mould and brought into bearing, the rest being covered and cropped in succession, as mushrooms may be in demand.

Mr Edward Callow, in a tract on the artificial growth of mushrooms, describes a method in which the pits are wrought by means of dung heat. His structure somewhat resembles Atkinson's melon-pit, only the roof is covered with thatch, and a suite of air-flues is formed within the interior of the pit, with branches crossing the principal bed which occupies the floor. Linings of fermenting litter are applied on the exterior of the house at the back and front. The atmosphere of the pit, in the earlier stage, is kept at 55° to 65° Fahrenheit, and when the bed is in full bearing, about 70°. The other details of this method scarcely differ from those of Mr Oldacre's.

KITCHEN GARDEN.

In this department those plants are cultivated which, after being subjected to various culinary processes, are used as articles of food. They may be enumerated in the order of their importance, each, for the sake of precision, being accompanied by its botanical name.

Cabbage Tribe.

The *Brassica oleracea*, Lin. is a plant indigenous to our rocky shores; but no one, seeing it waving in its native habitat, could possibly anticipate that it would ever appear in our gardens, disguised as the ponderous drumhead or sugar-loaf cabbage, or on our tables as the delicate cauliflower and broccoli. The cultivated varieties are numerous; but the following are the most important.

Common White Cabbage. The economical uses of this vegetable are well known. Its principal subvarieties are the following:

Small Early Dwarf,
Early May,
Dwarf Vanack,
Early York,
Chinese,
East Ham,
Large Sugar-loaf,
Drumhead,
Scotch,
Tronchuda.

The first three are adapted for early crops; the next three for use in the end of summer and autumn, and the others for winter. The leaf-stalks of the Tronchuda are used like sea-cale.

The Cabbage is propagated from seed, which may be sown in beds four feet wide, and covered over with a thin layer of earth. The proper seasons for this operation are the middle of August, the beginning of March, and Midsummer. By observing these times, and employing different sorts, the succession may be kept up through the year. For the early spring crops, the late sown plants are in October transferred from the seed-bed to some open and well manured ground, where they are arranged in rows two feet asunder. The principal supply may be put out in February, affording the larger sorts more width between the rows. The crops sown in spring are planted out in May and June. For subsequent culture, all that is necessary is, to keep the ground clear of weeds, and to draw up the soil about the stems. In some situations watering in summer is beneficial.

The cabbages grown late in autumn and in beginning of winter are denominated *Coleworts*, from a kindred vegetable no longer cultivated. The object is to have them with open or slightly closed hearts. Two sowings are made, in the middle of June and in July, and the seedlings, when they acquire sufficient strength, are planted out in lines, a foot or fifteen inches asunder, and eight or ten inches in the rows.

The Red Cabbage, of which the large or Dutch red is the common variety, is much used for pickling. It is sown along with the white varieties in August and in spring, and the culture is in every respect the same.

The Savoy. This variety, like the preceding, forms into a close head, but is distinguished by the wrinkling of its leaves. It is a very useful vegetable during the winter months. The principal subvarieties are the Early Green, the Yellow, and the Winter, of each of which there are various forms. The seed is sown in autumn and in the end of spring, and two plantings may take place, in April, and in June or July.

Brussels Sprouts. This vegetable is allied to the foregoing, but does not close or cabbage. From the axillæ of the stem-leaves proceed little rosettes or sprouts, which resemble savoy cabbages in miniature. The seed should be sown in spring, and the seedlings planted out before midsummer, during showery weather. In October the plants should have additional earth drawn to their roots, to firm them, and save them from being destroyed by frost. The earliest sprouts become fit for use in November, and they continue good, or even improving in quality, till the month of March following. Mr Van Mons of Brussels mentions (*London Hortic. Mem.* vol. iii.), that by successive sowings the sprouts are there obtained for the greater part of the year. In spring, when the plants have a tendency to run to flower, their growth is checked by lifting them, and replanting them in a slanting direction, in a cool shady situation.

Open Kale. The principal subvarieties are:

German Greens, or Curlies,
Scotch Kale, or Green Borecole,
Purple, or Brown Kale,
Delaware Greens,
Buda Kale,
Jerusalem Kale,
Woburn Kale.

Of these the three first are considered the most valuable, and are the sorts chiefly cultivated in this country. The seed is sown at various times from February to May, and the seedlings are planted out in moist weather during summer, in rows two feet asunder. The Buda Kale is sown in May, planted out in September, and being hardy, affords a supply in the following spring.

Of the Turnip-rooted Cabbage, or *Kohl-rübe*, there are two varieties, one swelling above ground, the other in it. There is nothing peculiar in the culture, unless that, in the case of the first mentioned, the earth should not be drawn so high as to cover the globular part of the stem, which is the part used. The seed may be sown in the beginning of June, and the seedlings transplanted in July; they are thus fit for use at the approach of winter.

Cauliflower. This variety is cultivated for the sake of the flower-buds, which form a large dense cluster or head, and afford one of the most delicate products of the

Kitchen Garden.

kitchen-garden. There are three subvarieties, the Early, the Late, and the Reddish-stalked; but these seem to present scarcely any well-marked distinction.

The sowing, for the first or spring crop, is made in the latter half of the month of August; and, in the neighbourhood of London, the growers adhere as nearly as possible to the 21st day. A second sowing takes place in February on a slight hot-bed, and a third in April or May.

The cauliflower being tender, the young plants require protection in winter. For this purpose they are sometimes pricked out in a warm situation at the foot of a wall with a southern exposure, where, in severe weather, they are also covered with hoops and mats. A better method is to plant them thickly in the ground under a common hot-bed frame, and to secure them from cold by coverings, and from damp, by giving air in mild weather. For a very early supply, it is useful to be at the pains of potting a few scores of plants; these are to be kept under glass during winter, and plunged out in spring, defending them with a hand-glass, and watering them when needful. Sometimes, as in market-gardens, patches of three or four plants are sheltered by hand-glasses throughout the winter in the open border. It is advantageous to prick out the spring-sown plants into some sheltered place, before they be finally transplanted and committed to the open ground in May. The later crop, the transplantation of which may take place at various times, is treated like early cabbages. Cauliflower succeeds best in a rich soil and a warm situation. After planting, all that is necessary is to hoe the ground, and draw up the soil about the roots.

It is found that this vegetable, being induced to form its large and crowded clusters of flower-buds in the autumn, may be kept in perfection over winter. Cauliflowers which have been planted out in July, will be nearly ready for use in October. Towards the end of that month, the most compact and best shaped are selected and lifted carefully with the spade, keeping a ball of earth attached to the roots. Some of the large outside leaves are removed, in order that the plants may occupy less room, and at the same time, any points of leaves that immediately overhang the flower are cut off. Where there are peach-houses or vineries the plants may be arranged in the borders of these, together, but without touching. Or they may be placed in the same manner in hot-bed frames: In mild dry weather the glass frames are drawn off, but they are kept close in rain; and in severe frost they are thickly covered with mats. In this way cauliflower may be kept in an excellent state for several months.

Broccoli has a close affinity to cauliflower, being, like it, of Italian origin, and differing chiefly in the greater hardiness of its constitution. The subvarieties are numerous, and exceedingly diversified. The following are those which are in most repute at present. The first five produce their buds in autumn, the others in spring:

Purple Cape,
Green Cape,
Grange's Early,
Early Purple,
Early White,
Cream-coloured,
Sulphur-coloured,
Spring White,
Late Purple,
Late Danish.

Of the autumnal sorts there should be two sowings, one in the middle of April, and one in the middle of May. As the plants acquire strength they are shifted into the open ground, where they are placed in lines two feet apart. The Cape varieties are of great excellence, being of a delicious flavour when dressed; but on account of the plants being apt to start into flower, their cultivation has in many places been neglected. With proper management, however, this tendency may be overruled. The first sowing may be made on any border of light soil, scattering the seed very sparingly. In about a month the plants may be transferred directly into a quarter consisting of sandy loam, well enriched with rotten dung. The greater part of the second crop should be planted in pots likewise directly from the seed-bed. These pots are to be sunk in the open ground till the heads be formed; and in the end of November they are to be placed under a glass frame, where very fine broccoli may be produced during the severest weather of winter. Mr Ronalds of Brentford recommends (*London Hortic. Trans.* vol. iii.) that the Early White, which is also a very fine sort, should be sown on a hot-bed, and treated like the secondary crop of cauliflower.

The spring varieties are extremely valuable, as they come at a season when the finer vegetables are scarce. They are sown in the middle of March or the beginning of April, and afford a supply from March to May inclusive of the following year.

To obtain seed of the Brassica tribe, true specimens of the different varieties should be selected, in such a state of advancement as that they will flower as early as possible in spring. They should be planted in an open situation, and kept as far apart from other kinds of the same tribe as may be. As they are very liable to *cross* or hybridize, it is perhaps better, except in the case of some favourite variety, to procure supplies from a respectable seedsman, from whom they are almost uniformly to be had genuine, the extensive seed-growers being at great pains to prevent intermixture of crops.

Leguminous Plants.

Of the Pea (*Pisum sativum*), there are two principal varieties, the Field or gray hog pea, and the Garden Pea. The latter alone requires our attention here. Its chief subvarieties are:

Early Frame,
Early Charlton,
Bishop's Dwarf,
Dwarf Marrowfat,
Tall Marrowfat,
Imperial,
Knight's Tall Marrowfat,
Dwarf Marrowfat,
Prussian Blue,
Prussian Green,
Leadman's Dwarf,
Sugar.

The first three are suitable for early crops, and the others for successional supplies. In the sugar pea, of which there are two sorts, the tall and dwarf, the inner filmy lining of the pod is absent, and the young legumes are used like kidney-beans.

The first crop of pease is sown about the beginning of November, in front of a south wall; and these, after they have appeared above ground, are defended by spruce-fir branches, or other spray, throughout the winter. In January and February other sowings are made, and sometimes the seed is put into flower-pots and boxes, and the young plants afterwards plunged out in spring. From the end of February moderate sowings should be made twice a month till the middle of August, thus ensuring a supply of successive crops of delicate green pease. For the latest crops the early frame and the Charlton are the best. Pease are sown in rows from three to five feet asunder, according to the height which the different sorts are known usually to attain. As they grow up the earth is drawn up to the roots, and the stems are supported with stakes, a practice which, in a well kept garden, is always advisable, although it is said that the early varieties, when recumbent, arrive sooner at maturity.

The early crops come into use in May and June, and by repeated sowings, the supplies are prolonged to November. Pease grown late in autumn are subject to mildew, to obviate which, Mr Knight has proposed the following method. The ground is dug over in the usual way, and the spaces to be occupied by the future rows of pease are well soaked with water. The mould on each side is then collected, so as to form ridges seven or eight inches high, and these ridges are well watered. On these the seed is sown in single rows. If dry weather at any time set in, water is supplied profusely once a-week. In this way the plants continue green and vigorous resisting mildew, and not yielding till subdued by frost.

Of the GARDEN-BEAN (*Faba vulgaris*), amongst many varieties may be mentioned:

The Early Mazagan,
Early Lisbon,
Dwarf Fan or Cluster,
Long Pod,
Green Genoa,
Windsor,
Green Windsor,
White-blossomed.

The Mazagan and Lisbon are sown in November, and are defended during winter in the same manner as early pease, but they are more difficult to preserve. The same sorts should be sown again in January and February. In March the Dwarf Cluster and Long-pod may be put in the ground for a general crop, and subsequently the Windsor and White-blossomed. The latter is a variety of considerable merit, and when the pods are taken at an early stage, they have little of the peculiar bean flavour, or only enough to render them pleasant. During the growth of the bean crop, all the culture that is necessary is, that the earth be drawn up about the roots. Topping the plants is usually practised, being found to promote the filling of the pods.

KIDNEY-BEAN. Under this general title are included the common kidney-bean (*Phaseolus vulgaris*, LIN.) of many varieties; and also the Scarlet Runner (*P. multiflorus*, WILLD.) Kidney-beans are the *haricots* of the French, who enumerate upwards of 200 varieties. The sorts usually cultivated in this country are,

Early Yellow,
Early Red Speckled,
Early Black,
Early White,
White Battersea,
White Canterbury,
Black Speckled,
Brown Speckled,
Scarlet Runner,
Dutch White.

The first four are the earliest; the others are more productive, and better fitted for a general crop. As the plant is of tropical origin, our climate is scarcely sufficient for the extensive cultivation of the ripe beans, which are the principal object in France and Italy. The immature legumes are chiefly used in this country.

It is seldom advantageous to sow kidney-beans in the open ground before the middle or end of April; after which period successive sowings may be made every fourteen days to the end of July. The plants are grown in rows two feet apart, and the earth is carefully drawn to the roots. Kidney-beans are well adapted for forcing, in hot-beds, or in hot-houses; the climate of the peach-house, when it can be obtained, being considered the best. The sowings may begin in January; they are made in pots, and a supply may be thus obtained in the months of March, April, and May. The dwarf speckled is commonly used in hot-houses, and the early white in hot-beds.

Esculent Roots.

The POTATO (*Solanum tuberosum*). This well-known plant is a native of the elevated regions of equatorial America. It was introduced into Europe about the middle of the 16th century, but remained little known or regarded till within the last hundred years: it is now so generally cultivated, as to have effected almost an economical revolution in this country. Most of the original British sorts were derived from Ireland. Its multitudinous varieties now set enumeration at defiance, and many are indeed appearing and disappearing every year. The culture of the late sorts properly belongs to the farm, and when the gardener has to take them under his care, he will find it best to adopt such as are common in the agriculture of the district. Of the early kinds, most of which are supposed to have originated in Lancashire, the following may be esteemed the best:

Kitchen Garden.

Early Royal Dwarf,
American Early,
Early Ash-leaved,
Early Frame,
Early Kidney,
Walnut-leaved Kidney.

Potatoes are commonly propagated by dividing the tubers, leaving to each segment one or two eyes or buds. The sets are then planted by the aid of the dibble or spade, in rows at a distance varying from fifteen inches to two feet. It has been suggested by Mr Knight (*London Hortic. Trans.* vol. vii.), and his views have been amply confirmed by experiment, that by planting whole tubers, and at greater distances, a larger produce will be obtained. Mr Knight proposed to leave four feet between the rows, a distance which, except with the larger varieties, was found to be too great. An experienced horticulturist in Scotland states, that by planting whole tubers, and by leaving in the case of dwarfs two feet, and in the tall varieties two feet and a half, between the rows, a return from one-third to one-half more was obtained than could be had from the old method. Of course a greater quantity of tubers are required for planting, but these bear no proportion to the great increase which results; and besides, early potatoes at the planting season being unfit for eating, there is little economy in sparing them.

The earliest crops should, if possible, be placed in a light soil and in a warm situation, and are planted about the middle of March. Sometimes the eyes of the tubers are made to spring or vegetate on a hot-bed, and the plants are put out as soon as the leaves can bear the open air. Perhaps it is better, as recommended by Mr Saul of Lancaster (*Gardener's Mag.* vol. ii.), to promote incipient vegetation in some warm place, as a house or greenhouse, by laying a woollen cloth or some other covering over them. When the sprouts are about two inches long, he plants them out towards the end of March, and thus procures young potatoes in seven or eight weeks. A secondary planting of tubers should be made before the middle of April. When the stems are a few inches above ground, the earth should be drawn to them; an operation, however, which, while it improves the crop, delays its maturity for two or three weeks. Mr Knight recommends removing the flowers as they appear, and states that by this means the produce is increased by a ton per acre. The fine early varieties, however, scarcely produce any flowers.

An important fact in the cultivation of the potato was observed about the year 1806, by the late Mr Thomas Dickson of Edinburgh, viz. that the most healthy and productive plants were to be obtained, by employing as seed-stock unripe tubers, or even by planting only the wet or least-ripened ends of long-shaped potatoes; and he proposed this as a preventive of the well-known disease called the *Curl.* This view has been confirmed by Mr Knight. An intelligent writer in the *Gardener's Magazine* (vol. ii. p. 171) states a method by which sprouting of the eyes is accelerated. He takes up the seed potatoes a considerable time before they are ripe, and exposes them for some weeks to the influence of a scorching sun. The resulting crop is at least a fortnight earlier; but it is not said how this practice affects the curl.

The forcing of early potatoes on hot-beds has long been practised; but it is attended with considerable trouble and expense. Small supplies of young waxy tubers are now often produced during winter, in boxes placed in a mushroom-house, or in a common cellar, if free from frost. In October, old potatoes are placed in layers, alternating with a mixture of tree leaves and light mould. Vegetation soon proceeds; and there being no opportunity for the unfolding of stems and leaves, the energies of the plants are expended in the production of young tubers. Before mid-winter these often attain the size and appearance of early potatoes; but they are much inferior, being watery and of little flavour.

Jerusalem Artichoke (*Helianthus tuberosus*), or tuberous-rooted sunflower. This plant, which is a native of Brazil, derives its epithet *Jerusalem* from a corruption of the Italian *Girasole*, a sunflower, and *Artichoke* from the resemblance, in flavour, which its tubers bear to the floral receptacles or *bottoms* of the artichoke. It is propagated by means of its tubers in the manner of potatoes. In March they are planted out in rows three or four feet asunder, and in autumn the new tubers are fit for use. For the sake of convenience, it is advantageous to store them, though the roots are hardy enough to bear the winter frosts. Some, indeed, allow them to remain in the ground, and dig them up when required. In this way a sufficient number of sets are generally left in the ground, and the stalks are thinned into rows in summer; but this is a slovenly mode of treatment, and seldom produces well-flavoured crops.

The Turnip (*Brassica Rapa*), like the potato, has, to a great extent, migrated into the fields, and become the care of the husbandman more than of the gardener. The following are the most esteemed garden sorts:

Early White Dutch,
Early Stone,
Green-topped White,
Long White,
Early Yellow Maltese,
Dutch Yellow,
Aberdeen Yellow,
Long Yellow.

Besides these, the *Navet* of the French (*Brassica Napus v. esculenta*) is occasionally cultivated, and more frequently the *Swedish Turnip* (*Brassica campestris v. Napo-brassica*, L.), which is a most excellent winter sort, though it belongs more properly to the farm. For early crops, the white Dutch is the principal variety; the other white sorts, and the beautiful yellow Maltese, are useful in summer and in the beginning of autumn. The yellow Dutch being capable of enduring any degree of frost, affords the best winter supplies.

Turnips succeed best in a rich, well-worked soil, of a light or medium quality. The first sowing is made about the end of March, in a warm situation; and it is usual to put in additional sowings, once a fortnight or three weeks, till the end of August. The early crops are sown *broadcast*, and the later in drills. After the plants have shewn a rough leaf or two, they are thinned out, being left at the distance of eight or ten inches in the drill; and the ground is hoed and kept free from weeds. As turnips which have stood the winter throw up their seed-stalks early in spring, after which their roots become stringy, and are much deteriorated, it is useful to store the turnips in winter, keeping them in a close place, and covering them with straw.

The young plants, while in the seed-leaf, are often destroyed by a small beetle called the turnip-fly (*Haltica nemorum*). Many remedies have been proposed: it has been found beneficial to dust the rows with quicklime; but perhaps the best precaution is to sow thick, and thus insure a sufficient supply both for the insect and the crop.

The Carrot (*Daucus Carota*) is one of our native Umbelliferæ, but has been much transformed by cultivation. The best varieties are the Early Horn and the Orange Carrot, the former for early, the latter for general cultivation. The carrot loves a light, deep, fresh soil, in which it may be at liberty to push down its long spindle-shaped roots. A few Early Horn carrots may be sown in February on a moderate hot-bed. In the beginning of March, the same sort may be sown in the open air. In April, the orange variety may follow as a general crop: it succeeds best in drills. In many old gardens the early plants are liable to the attacks of a small grub, the larva of some insect; it is therefore a useful precaution to sow a moderate crop of the Early Horn variety in July. After sowing, it is only necessary to thin the plants and keep them clear of weeds. The roots are stored in winter in the manner of turnips.

The Parsnep (*Pastinaca sativa*) is now less cultivated than it was in Catholic times, when it was a favourite accompaniment to dried fish in Lent. To some its flavour is not agreeable; but it is a very nutritious vegetable, and of easy digestion. Like the carrot, its root is long and tapering, differing chiefly in being of a whitish colour. Its culture is also very much the same.

Red Beet (*Beta vulgaris*) is a biennial plant, a native of the shores of the south of Europe. The boiled root is eaten cold, either by itself or as a salad: it is also often used as a pickle. The varieties are numerous, but the most common are the Long-rooted, the Short or Turnip-rooted, the Bassano, and the Green-topped. There is a fine French variety called Castelnaudary, from a town in Languedoc; but as yet it is little known in this country.

Red beet prospers in a rich, deep soil, not recently manured, and which has been well pulverized by the spade. During April the seeds may be sown in drills, fifteen inches asunder, and the plants are afterwards to be thinned to eight inches from each other in the lines. In the northern parts of the island, the roots are stored in winter, care being taken not to break them or cut off the leaves too closely, as they bleed when injured.

Skirret (*Sium Sisarum*) is a native of China, now seldom seen in our gardens. Its tubers are used like parsneps. It is a perennial, and may be propagated by separating the roots in spring; but it succeeds better by annual sowings, which may be made in April.

Scorzonera (*Scorzonera Hispanica*) and Salsify (*Tragopogon porrifolius*) are generally associated together in gardens, and are now less cultivated than they deserve. The roots are used in soups, and sometimes as dressed side dishes. They are sown in lines, and treated like the crops of red beet or parsnep.

The Radish (*Raphanus sativus*) is a native of China. There are two principal varieties, the spindle-rooted and the turnip-rooted radish; and of these the subvarieties are numerous. The following may be mentioned:

Early Frame Scarlet,
Short-topped Scarlet,
Scarlet Salmon,
Long White,
White Turnip,
Yellow Turnip,
White Spanish,
Black Spanish.

The first two and the white turnip radish are best suited for early crops; the scarlet salmon for summer, the yellow turnip for autumn, and the white and black Spanish for winter.

Some cultivators sow their earliest crop in November, in a warm situation, at the foot of a wall or in front of a pinery, and continue sowing once a-month, if weather permit, during winter. Others grow their first radishes under frames, aiding vegetation by a slight bottom heat. As the season advances, successional supplies are sown once a fortnight. From the middle of July to the middle of September, the turnip-radishes are sown from time to time; and on the approach of frost they may be stored up in sand like carrots, and kept throughout winter.

Oxalis Roots (*Oxalis crenata*, Jacq.; *O. arracacha*, G. Don) have of late years been cultivated for the table in this country. The plant produces tubers at the root, somewhat in the manner of the potato; but they are of small size, seldom exceeding that of a walnut. By cultivation, however, by manuring, laying down, earthing up, watering, and other helps known to horticulturists, considerable increase of size in the tubers may be effected. From the mode of culture adopted by the most intelligent gardeners, we conclude that a rich light soil is the most proper (although some cultivators have recommended a poor soil); that it is useful to forward the plants in a hot-bed, in the way practised with early pease, so as to have them ready to transplant by the middle or end of May; that in planting out, they should be inserted in a sloping position, so that a considerable portion of the stem may be covered by the soil; that earthing up, or drawing up additional soil to the stems in June and July is important; and that laying down the stems horizontally in August, and covering them slightly (to the depth perhaps of two inches) with mould, tends greatly to promote the productiveness. It should be observed that the tubers continue to swell in size till November, or till stopped by frost. It is believed that the largest tubers, having full eyes or buds, yield the strongest plants; and therefore a portion of the largest should always be reserved for seed-stock. Cut sets of these large tubers are, by some cultivators, preferred to whole tubers. The rest, from the size of a filbert to a walnut, go to the cook. We may remark, that till the plant become more common, the very smallest tubers should not be thrown away, but should be carefully preserved, for increasing the extent of the oxalis bed the following season. The mode of dressing for table is simple. The tubers, after being cleaned, are boiled for about ten minutes, or till they be slightly softened; and they are then served up with white sauce. Some persons merely put them into boiling water for a few minutes; then, pouring off the water, transfer them to a covered saucepan; and place the pan upon hot cinders, drawing some of these near to the lid: in this way the tubers are rendered more dry or mealy. They are of excellent quality and pleasant flavour; somewhat resembling a new potato, with the additional zest of a nut or kernel. The oxalis comes from the same country that afforded us the invaluable potato, and has been extolled as likely to rival it; but this it will never do: a dish of oxalis will form an agreeable variety and adjunct, but no more; bearing to the potato such relation as sea-cale does to asparagus. It may be added, however, that the oxalis crenata is, in other respects, a useful vegetable. The leaves may be used as salad, and form, indeed, the principal salad at Lima. The shoots and young branches are found to make a pleasant purée, having the wood-sorrel flavour; and the larger stems have been used in tarts, in the manner of rhubarb-stalks, and been found more tender.

Alliaceous Plants.

The Onion (*Allium Cepa*) is too well known to require description: it has been cultivated in this country from time immemorial. Among the varieties may be enumerated:

Strasburgh,
Deptford,
Globe,
James's Keeping,
Silver-skinned,
White Portugal,
Blood Red,
Potato Onion.

Besides these, the Welsh Onion or Ciboule (*Allium fistulosum*, L.), a native of Siberia, is sometimes grown for scallions. For a general crop, the Strasburgh and Deptford varieties may be esteemed the best. The White Portugal grows to a large size, but does not keep well. The silver-skinned is chiefly used for pickling.

The onion affects a light, rich. well worked soil, which has not been recently manured The principal crop may be sown in the course of the month of March, according to the state of the weather and the dryness of the ground. Onions are grown in beds, four or five feet in width, and are regularly thinned, hoed, and kept free from weeds. About the beginning of September the crop is ripe, which is known by the withering of the leaves; the roots are taken up, and, after being well dried, are stored in a garret or loft, where they may be perfectly secured from damp.

Towards the end of August a secondary crop is sown, to afford a supply of young onions or *scallions*, as they are called, in the spring months. The Strasburgh and White Portugal may be used for this purpose. Those which are not required for the kitchen being allowed to stand, if the flower-bud is picked out on its first appearance, and the earth is stirred about them, frequently produce bulbs equal in size and quality to the large ones that are imported from the Continent.

Some eminent horticulturists have strongly recommended the transplanting of onions. Mr Knight sows the White Portugal onion in spring under the shade of a tree, where they remain of a diminutive size. They are kept over winter, and are planted out in the succeeding spring. Mr Brown collects all the minute bulbs of the ordinary crop, and uses them in the same way. Mr Macdonald, Dalkeith Park, confines his operations to one summer. He sows in February on a slight hot-bed, or sometimes merely under a glass frame. In the first or second week of April, according to the state of the weather, he transplants the young seedlings in rows, eight inches asunder, and at the distance of four or five inches in the row. Previously to planting, the roots of the seedlings are dipped in a puddle of one part of soot to three parts of earth, an expedient which is found to secure the transplanted onions from the wire-worm. Onions thus treated attain a large size. We have seen autumn-sown onions submitted to a similar management with great success.

The Potato Onion is propagated by the lateral bulbs, which it throws out, under ground, in considerable numbers. It is planted about mid-winter, and ripens in summer. Its flavour is strong, and not unpleasant; but the plant being rather delicate and troublesome in cultivation, is not likely to supersede the common onion.

The Pearl Onion, of recent introduction, and hitherto little known, produces clusters of small bulbs at the root. These little bulbs are of a fine white colour, like the silver-skinned onion, and very fit for pickling.

The Leek (*Allium Porrum*) is a native of Switzerland, but has probably been cultivated in this island for many centuries. The varieties are the narrow-leaved or Flanders leek, the Scotch or flag leek, and the broad-leaved or tall London leek. Of these the Scotch leek is considered as the most hardy.

Leeks are sown in beds in spring; and in June or July are planted out in rows fifteen or eighteen inches apart, and six inches asunder between the rows. The tips of the fibrous roots are trimmed before planting. When the weather is moist, it is found beneficial merely to lay the plant into the hole made by the dibble, without closing the earth upon it, the stem being by this means encouraged to swell out and fill the hole.

Shallot (*Allium ascalonicum*) is a native of Palestine. It is much used in cookery for high-flavoured soups and gravies, and is sometimes put into pickles. It is propagated by off-sets, which are commonly planted in September or October. Some recommend the mixing of soot with the manure as a protection against maggots, by which this plant is greatly infested. Autumn planting, however, is found the best expedient, as the bulbs are ripe before the larvæ commence their depredations.

Garlic (*Allium sativum*) and Rocambole (*Allium Scorodoprasum*), though common ingredients in continental cookery, are comparatively seldom used in this country. A few rows will generally be found sufficient. They are propagated by offsets from the roots, or by the bulbils which grow on the flower-stem. The Chive or *Cive* (*Allium Schoenoprasum*), a pleasant little native plant, is used occasionally as salad and alliaceous seasoning. A single row may be planted as an edging to an onion bed, and it is easily increased by parting the roots in spring and autumn.

Spinaceous Plants.

Spinach (*Spinacia oleracea*) is an annual plant, and is a native of Western Asia. It has long been cultivated for the sake of its succulent leaves, which, when properly dressed, form a pleasant and nutritious article of food. There are two varieties; the round-leaved or smooth-seeded, and the angular-leaved or prickly-seeded. The latter, as being the most hardy, is used for the winter crop.

The first sowing is made in August, in some sheltered situation; the plants, as they advance, are thinned, and the ground is hoed. In the beginning of winter the outer leaves become fit for use; in mild weather, successive gatherings are obtained, and, with proper management, the crop may be prolonged to the beginning of May.

To afford a succession crop, the seeds of the round-leaved variety should be sown in the end of January, and again in February and March. From this period it is proper to sow small quantities once a fortnight, summer spinach lasting only a very short time. The open spaces between the lines of cauliflower, and others of the cabbage tribe, will generally afford enough of room for these transient crops. They are generally sown in shallow drills, and are thinned out and weeded as may be required.

White Beet (*Beta Cicla*) is cultivated for the leaves, which are used as spinach. The midribs and stalks of the great white beet, when separated from the leaves, are stewed and eaten as asparagus, under the name of Swiss Chard. The culture does not differ materially from that of the red beet.

New Zealand Spinach (*Tetragonia expansa*) is a half-hardy annual, a native of New Zealand, from which it was brought by the late Sir Joseph Banks. It is an excellent substitute for spinach; and if well watered, it will continue to afford large quantities of succulent leaves during the hottest weather. It is sown in a pot placed in a melon-frame in March: the seedlings are transplanted into small pots, and kept under cover till the beginning of June, when they are plunged out at two or three feet apart, and treated somewhat like gourds. In gathering the leaves, care must be taken not to injure the leading shoots.

Quinoa Spinach (*Chenopodium Quinoa*). This vegetable is a native not only of Chile, but of the table land of Mexico. It is described and figured by Ruiz and Pavon, and Humboldt informs us, that in Mexico the leaves are universally used as spinach or greens, and the seeds in soups, or like rice, so that quinoa there vies in utility with the potato itself. Although the plant had been known in Britain for a number of years, it was only during the autumn of 1834 that any considerable portion of seed was ripened or saved in this country. This was accomplished at Boyton in Wiltshire, by Mr Aylmer Bourke Lambert, the well known patron of botany and horticulture. Considering the elevated region in America in which the quinoa is successfully cultivated, there can be no doubt that its herbage will be freely produced in this country; but it seems probable that, in order to secure the ripening of seeds, it may be requisite to place some plants close by a wall having a south or south-west aspect, as is practised with seeding onions; more especially since we are warned by Willdenow, that, in Germany, "semina sub dio non semper perficit." There are two varieties, the common white-seeded or green quinoa, and the dark-seeded or red quinoa, the former seemingly the more hardy, or at least germinating most freely.

Garden Orache (*Atriplex hortensis*), Wild Spinach (*Chenopodium Bonus Henricus*), and Garden Patience (*Rumex Patientia*), are sometimes used in place of common spinach; but as, in this country at least, they are deemed rather curious than useful, it may be sufficient to indicate their names.

Asparaginous Plants.

Asparagus (*Asparagus officinalis*) is a perennial plant, a native of the shores of Britain, where it occurs sparingly, and of the steppes in the east of Europe. Though somewhat unpromising while in a state of nature, it affords, in cultivation, an esculent of considerable value, and is therefore grown extensively both in private and in sale gardens. The principal varieties are the *red-topped* and the *green-topped*, of which the latter, while it is less succulent, is considered the better flavoured. There are numerous subvarieties, such as the Battersea, Gravesend, Giant, &c., which differ only slightly or not at all from those already mentioned.

Asparagus, growing naturally on loose sand, loves a light deep soil, through which it may be able to shoot its long stringy roots. Two feet and a half is considered a desirable depth, but in France the ground is sometimes prepared, by sifting, to the double of that depth. A considerable portion of well-rotted dung or of recent sea-weed is laid in the bottom of the trench, which may be from two to three feet deep; and another top-dressing of manure should be digged in preparatory to planting or sowing. The older horticulturists used to grow their asparagus in beds four or five feet wide, with intervening alleys of about eighteen inches in breadth. At present, in Scotland, it is customary to sow or plant in rows from three to four feet asunder; a method which, in every way, is found to be most convenient. Except where the garden is new, when, of course, it is advantageous to procure a supply of ready grown plants, it is thought preferable to keep up the stock of asparagus by sowing.

The sowing is made in March, in slight drills; and, as a portion of the seed often fails to germinate, it is a good precaution to employ about double the quantity of seed that may be ultimately necessary. If the plants come up too thickly, they may be thinned out towards the end of the first summer, to the distance of about six inches in the rows. The ground is hoed, and kept clear of weeds. It is a common practice to take slight crops of onions, lettuce, cauliflower, or turnip, between the lines of asparagus during the first, and, if the rows be wide, also in the second year. The young heads or stalks, the part used, should not be cut before the third spring, and they are not in perfection till the fourth or fifth.

The asparagus quarter can scarcely be over manured. The proper time to perform this operation is in the end of autumn, when the annual flower-stalks are removed, preparatory for winter. When beds are employed, their surface should be stirred with a fork; a layer of well-rotted hot-bed dung is then laid on, and the whole covered with a sprinkling of earth from the alleys. If the plants are grown in rows, the manure is simply dug in by means of a three-pronged fork, care being taken not to injure the roots. This operation is repeated annually. No other culture is required; but it is necessary to observe a due moderation in reaping the crop, as the shoots, when much cut, become progressively smaller and less valuable. Hence a considerable quantity of ground is required for the cultivation of this vegetable, and it is a general rule never to gather it after pease have come into season.

Asparagus readily admits of being *forced.* The most common method is to prepare, early in the year, a moderate hot-bed of stable litter, and to cover it with a common frame. After the heat of fermentation has somewhat subsided, the surface of the bed is lined with turf, to prevent the escape of vapour; a layer of light earth or exhausted tan-bark is put over the turf, and in this the roots of plants five or six years old are closely placed. The crowns of the roots are then covered with two or three inches of soil. A common three-light frame may hold 500 or 600 plants, and will afford a supply for several weeks. After planting, linings are applied when necessary, and air is occasionally admitted. Care must be taken not to scorch the roots. Where there are pits for the culture of late melons or succession pine plants, such as the Alderston pit, or the succession pit with the hot-water circulation, they may advantageously be applied to this purpose.

It has been recommended (*Lond. Hortic. Trans.* vol. v.) to force asparagus on the ground on which it grows. Perhaps the best method is that suggested by Mr Spiers in vol. iv. of the Gardener's Magazine. The seed is sown in beds four feet eight inches wide, and there are four rows of plants, eleven inches asunder in the bed. The beds are lined by a pigeon-hole brickwork two feet deep, an operation which we presume need not be performed till immediately before forcing, that is, when the plants are at least four years old. In October, when the stalks are cleared away, the surface is covered with littery straw. When forcing is commenced, the brick-lined trenches are filled with hot stable-dung, well beaten, to about eighteen inches above the surface of the ground. The bed is also covered with prepared dung. In about twelve days, when the buds have begun to appear, the latter covering is removed, glazed frames are placed upon the brick-work, a little fine soil is sifted over the plants, the linings in the trenches are raised higher, and the whole treated like a common hot-bed. In this way, we are informed, excellent supplies may be obtained, and the plants may be forced every year.

Before leaving this subject, it may be mentioned, that about Bath, the young flower-spikes of *Ornithogalum pyrenaicum,* found native in that neighbourhood, are used like asparagus, under the name of *Prussian grass.*

Sea-kale (*Crambe maritima*) is a perennial plant, growing spontaneously on the shores of the southern parts of the island. The roots are spreading, the leaves waved, glaucous, and covered with a fine mealy bloom, and the stalks rise to about two feet high, bearing white flowers which smell of honey, followed by seed-pods, each containing a single seed.

The country people in the west of England have long been accustomed to use in spring the young shoots, which, by passing through the sand and gravel on which they grow, are somewhat blanched and rendered tender. In conformity with this practice, the cultivation formerly recommended consisted merely in covering the beds on the approach of spring with a little dry earth or sand, in order to the blanching or intenerating of the shoots. These were cut as they appeared in March and April. Now, however, the blanching is not only much more completely effected, but simple means have been devised for supplying the table for half the year, including all the winter months. It has, within these few years, become a vegetable of common occurrence in the markets both of London and Edinburgh.

Sea-kale seems partial to a light dry soil. If manure be added, it should consist of sea-weed or leaves of trees. The plants may be propagated by offsets, or small pieces of the roots having buds or eyes attached to them; but the most eligible method is by seed. We have seen very tolerable blanched stalks produced by plants only nine months old from the seed, and after two summers, seedling plants will have acquired sufficient strength for general cropping. The sowing is made in March, the seeds being deposited in patches of three or four together, the patches being arranged in lines three feet apart, and two feet in the line. In order to secure a succession, and to obviate the bad effects of forcing, it is proper to sow a few lines of sea-kale every year.

Various modes of blanching the shoots have been resorted to. In the first volume of the *Memoirs of the Caledonian Horticultural Society,* Sir George Mackenzie describes a very convenient method. The sea-kale bed is merely covered, early in spring, with clean and dry oat-straw, which is removed as often as it becomes dry and musty. The shoots rise through the straw, and are at the same time pretty well blanched. Others employ dried tree-leaves for this purpose. Another method practised by many gardeners consists in placing over each plant a flower-pot of the largest size inverted; but convenient *blanching-pots,* with moveable lids, have been constructed for the express purpose. It may be proper to provide from thirty to sixty such pots; and it may be expected that each pot will, on an average, furnish a dish and a half of shoots during the season.

With the aid of these pots, sea-kale is *forced* in the open border in the way now to be described. In the latter end of autumn a bed of vigorous sea-kale plants is dressed, that is, the stalks are cut over, and the decayed leaves are removed. The ground is, at the same time, loosened about the eyes, and a thin stratum of gravel or sifted coal-ashes is laid on the surface to keep down earth-worms. A pot with a moveable cover is placed over each plant or each patch of plants. Stable-litter is then closely packed all round the pots, and raised up to about a foot above them; the whole thus assuming the form and appearance of a large hot-bed. When fermentation commences, a thermometer should be occasionally introduced into a few of the pots, to ascertain that the temperature within does not exceed 60° Fahrenheit, and the depth of the litter is to be regulated accordingly. The vegetation of the included plants is speedily promoted; so that, in the space of a month or six weeks, the shoots will be ready for cutting, which, being thus excluded from the light, are most effectually blanched, and are exceedingly tender and crisp. By means of the moveable lids, the plants are examined and the shoots gathered without materially disturbing the litter. By commencing at various times, a supply for the table can be readily furnished from the middle of November till the middle of May.

The Artichoke (*Cynara Scolymus*) is a perennial plant, a native of the south of Europe, and is a well known inhabitant of our gardens. It resembles a thistle on a large scale. In France, the entire head or whole leaves of the involucre of the artichoke are eaten, when in a young and tender state, *en poivrade,* or with pepper, salt, and vinegar; but in this country the only parts used are the base of the leaves of the involucre, and the immature floral receptacle, or phoranthium, commonly called the *bottom,* freed from the bristly seed-down which has been called the *choke.* The varieties are the conical or French, the globe or red artichoke, and the dwarf globe. Of these the first is the highest flavoured, the second is well adapted for a general crop, and the third is prolific, and occupies little room.

The artichoke loves a deep cool dry soil. It is propagated by parting the roots in April, the sets being planted in rows four or five feet asunder, and two feet apart in the rows. The young plants generally afford a crop which succeeds that of old plants; and for this reason a new plan-

Kitchen Garden.

tation is made in some gardens every year. During summer the plants are kept clear of weeds, but require little other attention. In November the decayed stems and leaves are removed, and the ground cleared. In some gardens the earth is ridged slightly around the roots, in order to defend the stools from the frost. This, however, is done more effectually by a litter of straw, or of the refuse of the stable-yard, of the depth of a foot, drawn close round the base of the leaves. In April this litter is taken away, the stocks are examined, and two or three only of the strongest shoots are permitted to remain. The offsets, which are carefully removed, afford materials for a young plantation. The ground between the rows is digged over. At this time manure may be applied; well-rotted hot-bed dung, and above all sea-weed, being considered preferable.

The Cardoon (*Cynara Cardunculus*) is a perennial plant, a native of the south of France and Spain. It has a close resemblance to the artichoke, but surpasses it in size. The edible part, or *chard*, as it is called, is composed of the blanched and crisp stalks of the inner leaves. Besides the common sort there is a prickly variety, known in France by the name of the Cardoon of Tours. The common artichoke is also used for the production of chard. Cardoons are found to prosper on light deep soil. The seed is sown annually about the middle of May, in shallow trenches, like those for celery, and the plants are thinned out to ten or twelve inches from each other in the lines. In dry weather water is copiously supplied, not only to increase the succulence of the leaves, but to prevent the formation of flower-stalks, which render the plant useless. In autumn the leaves are applied close to each other, and wrapped round with bands of hay or straw, the points of the leaves only being left free. Earth is then drawn up around the leaf-stems to the height of fifteen or eighteen inches. Sometimes cardoons are blanched by a more thorough earthing up, in the manner of celery, but in this case the operation must be carried on from the end of summer. During severe frost the tops of the leaves should be defended with straw or litter.

The Rampion (*Campanula Rapunculus*) is an English native biennial, the roots of which, under the name of *ramps*, are used as a salad, or boiled like asparagus. It is but little cultivated in this country. The seed is sown broadcast, about the beginning of June, in a cool situation, and the young plants are merely to be thinned and kept clear of weeds. On the approach of frost, the roots, which somewhat resemble small radishes, are stored in sand, and will keep fresh and firm till spring.

Salads, &c.

Lettuce (*Lactuca sativa*) is a hardy annual, but of what country it is a native is unknown. Some suppose it to be a seminal variety of the native *L. virosa*, a poisonous plant, "which," says Professor Lindley, "would not be more remarkable than the fact, that the indigenous celery is one of our strongest poisons." Besides its well known uses, it may be mentioned that the late Dr Duncan senior, of Edinburgh, prepared from its milky juice, a medicine denominated *Lactucarium*, similar in its action to opium, but capable of being administered in cases where that powerful drug is inadmissible. There are two principal varieties, the Cos or upright, and the Cabbage-lettuce. The subvarieties are numerous; we may mention the following:

Early Forcing Cos,
Green Cos,
White Cos,
Cilicia,
White Cabbage,
Brown Dutch Cabbage,
Imperial Cabbage,
Grand Admiral.

By proper care fresh lettuce may be had throughout the whole year. The first sowing is made in January, in some sheltered situation, or under hand-glasses, or in February on a gentle hot-bed. The seedlings are transplanted as soon as the weather will permit. A second sowing may be made in the beginning of March, and another in April. Besides the ordinary compartments, the seedlings may be planted on celery ridges, between rows of slight crops of other vegetables, and, in short, in any odd corner which may occur. To obtain a winter supply, a sowing is made in August or September, and the plants are pricked out in October, along the bottom of walls, or under glazed frames.

Endive (*Cichorium Endivia*) is an annual plant, a native of China, from which it was introduced in 1548. It is the lettuce of winter, the blanched hearts being used for salads and in soups. The varieties are, the Broad-leaved Batavian, the Green Curled-leaved, and the White Curled-leaved. A sowing may be made in the beginning of June, and another in July, the seeds being scattered very sparsely, that the plants may not come up in clusters. The seedlings are transplanted into a rich soil, and are arranged in rows twelve or fifteen inches asunder, and at the distance of ten inches in the row. Sometimes they are planted in drills to facilitate the operation of blanching. The later crop should be placed in a sheltered situation, where it may be able to withstand the winter. When the plants have reached their maturity, the leaves are gathered up, and tied together an inch or two below the tips, and afterwards about the middle of the plant. In two or three weeks they are found sufficiently blanched for use. In winter it is necessary to draw the earth quite up about the leaves. At that season, too, the plants may be inserted into a sloping bank of earth, or blanched in boxes in the mushroom-house, or in a cellar.

Succory (*Cichorium Intybus*) is an indigenous plant, the cultivation of which may be said to have been introduced by the foreign refugees during the French revolutionary war. By the French it is much esteemed as a winter salad, and, when blanched, is known by the name of *Barbe du Capucin*. When intended for winter use, the seed is sown in May or June, commonly in drills, and the plants are thinned out to four inches apart. If the first set of leaves grow very strong, owing to wet weather, they are cut off perhaps in the middle of August, about an inch from the ground, so as to promote the production of new leaves, and check the formation of flower-stems. About the beginning of October the plants are raised from the border; all the large leaves are cut off; the roots are also shortened. They are then planted pretty closely together in boxes filled with rich light mould, and watered when needful. When frost comes on, the boxes are protected by any kind of haulm. As the salad is wanted, they are removed into some place having a moderately increased temperature, but with little light, such as a mushroom-house or cellar off the kitchen. Each box affords two crops of blanched leaves, and these are reckoned fit for cutting when about six inches long. The roots of this plant, it may be added, have been employed as a substitute for coffee-beans, and in Flanders, and some parts of France, a portion of them is very often mixed with coffee.

Parsley (*Apium Petroselinum*) is a biennial plant, of well-known use in cookery. It is said to be a native of Sardinia, but it now grows spontaneously in various parts of Britain. The varieties are the Common, the Curled-leaved, and the Hamburg, the last of which is cultivated for the sake of its tuberous roots. Parsley loves a light rich soil. It is sown in drills about the beginning of March, and the seed lies some weeks in the ground before the plants appear. As they grow up they are thinned out, and they are defended by branches or other coverings from hard weather in winter. The Hamburg variety being cultivated for its roots, is sown about the same time in a well trenched soil, in drills a foot apart, and it is thinned to about nine inches in the rows. In the beginning of November the roots are taken up and stored in sand.

Celery (*Apium graveolens*) is a native biennial, an inhabitant of the sides of ditches near the sea. In its wild state it is of an acrid nature, and of a coarse, rank flavour; but by cultivation it is improved into one of the most agreeable salads. There are two principal varieties; *celery* properly so called, with upright stalks and fibrous or slightly tuberous roots; and *celeriac* with large turnip-shaped roots. Of the former, the principal subvarieties are, the Italian, the Red Solid, and the White Solid, of which the second and third are the best.

Celery is usually sown at three different times: on a hot-bed in the beginning of March, and in the open ground in March, and again in April. The seedlings, when about two inches high, are pricked into rich soil, in which they are allowed to stand till they are four or five inches high. The first crop is defended by frames or hand-glasses, and is planted wide to admit of being lifted with balls of earth adhering to the roots. Towards the end of May trenches for blanching the celery are prepared. These trenches are three and a half or four feet apart, fifteen inches wide at the bottom, and about a foot below the natural level of the surface. The soil at the bottom of the trench is carefully digged and manured, and a single row of plants is placed in each trench. Sometimes where a large supply is required, the trenches are made six feet wide, and after a similar preparation, rows fifteen or eighteen inches apart are planted across the trenches. As the plants advance in growth, earth is laid up about the stalks of the leaves, an operation which is repeated at the end of every ten or fifteen days, care being taken not to choke the plants. As the celery approaches maturity, scarcely any thing but the tips of the leaves appear above the ridges, and, when lifted, the stalks are found to be completely blanched. Successional crops should then be planted out. Celery loves a rich light soil and an abundance of moisture.

Celeriac, or turnip-rooted celery, is treated at first like the early crop of common celery. In the beginning or middle of June it is planted out in a flat bed, in drills fifteen inches apart. A single earthing afterwards suffices. Its large round roots are used in soups, and are much relished by some. It is, however, more attended to in France and the Low Countries than in Britain.

Garden Cress (*Lepidium sativum*), and White Mustard (*Sinapis alba*), are generally associated in their use as salads, and in their culture in the garden. They are annual plants, and are eaten only when very young. In winter they may be raised on a slight hot-bed, in spring under hand-glasses, or in drills near a south wall, and in summer, when they should be sown once a fortnight, in drills, in any cool shady situation. Table mustard, which is made from *Sinapis nigra* L., belongs rather to the department of agriculture. Durham mustard, which is distinguished for its poignancy, though not remarkable for fine colour, is said to be made principally from the seeds of the common yellow field mustard or charlock, *Sinapis arvensis* L.

Of Rhubarb (*Rheum*) several species and many varieties are cultivated for the purpose of supplying materials for tarts, the foot-stalks of the leaves being well adapted for that purpose, and coming into use at a most convenient season. R. *rhaponticum* and *palmatum* were the species first employed, and are still occasionally used; but the sorts now preferred are seminal varieties, mostly allied to *R. hybridum* and *R. undulatum*. The following are the most worthy of notice:

Wilmot's,
Gigantic,
Elford,
Buck's.

Of these, the talented editor of the *Horticultural Register* decidedly prefers the first two, the former as being excellently suited for forcing, the latter as growing to a great size, without rankness. They may be multiplied by dividing the roots, and this is the common practice; but they thrive much better when grown from seed. Mr Paxton recommends sowing on a slight hot-bed in spring, and transplanting out in rows in the month of May. No stalks are gathered from them for the first two years, but in the third season they are fit for use. A portion of the crop is allowed to come on under the general influence of the season; but much also is forced, which may be done in a variety of ways. Some treat it like sea-kale, covering the root allowed to remain in the ground with a large pot or box, and wrapping it round with litter. Others take up the roots in autumn, pot them, and force them in vineries or hot-beds. Perhaps the best method is to procure long narrow boxes of a moderate depth, and to place them, packed full of roots, in a mushroom-house or cellar, where there is a considerable temperature. The rhubarb soon throws up its stalks, and these being partially etiolated, possess a delicacy and flavour superior to those grown in the open air. It is easy, by varying the time of subjecting the boxes to the increased temperature, to keep up a succession of rhubarb stalks, from the period at which kitchen apples become scarce or begin to lose their flavour, till green gooseberries come into season.

The following annual plants are occasionally used in cookery, or as salads: *Chervil*, Scandix cerefolia; *Purslane*, Portulaca oleracea; *Lamb's-Lettuce*, Fedia olitoria; *Indian Cress*, Tropæolum majus; *Marigold*, Calendula officinalis; *Borage*, Borago officinalis. These may be sown in spring, or in the beginning of summer, in any fresh light soils. In general a small quantity will suffice.

The *Common Sorrel*, Rumex acetosa; and the *French Sorrel*, Rumex scutatus; and the *Horse-radish*, Cochlearia Armoracia, are perennials, and are increased by parting their roots. They thrive in any cool shady situation.

The *Capsicum* or *Chili*, Capsicum annuum, and the *Love-Apple*, Solanum Lycopersicum, are tender annuals from tropical climates. Both are sown in hot-beds in spring, and after being transplanted and nursed in separate pots, are planted out, the former in a warm border, and the latter against a wall. In Scotland the Capsicum will scarcely mature its fruit without the aid of glass.

Dill, Anethum graveolens, and *Angelica*, Angelica archangelica, are umbelliferous biennials, which have been for a long period, though not extensively, cultivated in our gardens. They are easily raised from seed. With these may be associated the beautiful perennial, *Fennel*, Anethum Fœniculum, used in salads and sauces. It may be propagated either by parting the roots, or by seeds, which should be sown in autumn, soon after they are ripe.

In every garden there is a small department set apart for the culture of Sweet Herbs and Medicinal Plants. We need not here enter into details respecting their uses or culture, but shall merely give classified lists.

Shrubby Plants increased by parting the roots, or by cuttings:—*Thyme*, Thymus vulgaris; *Sage*, Salvia officinalis; *Winter Savory*, Satureja montana; *Rosemary*, Rosmarinus officinalis; *Lavender*, Lavandula Spica; *Hyssop*, Hyssopus officinalis; and *Rue*, Ruta graveolens.

Perennial Herbaceous Plants, increased by parting the roots:—*Spearmint*, Mentha viridis; *Peppermint*, M. piperita; *Pennyroyal*, M. pulegium; *Balm*, Melissa officinalis; *Tarragon*, Artemisia Dracunculus; *Tansy*, Tanacetum vulgare; *Costmary*, Balsamita vulgaris; *Chamomile*, Anthemis nobilis.

Biennial or Annual Plants, increased by sowing the seeds:—*Clary*, Salvia Sclarea; *Coriander*, Coriandrum sativum; *Caraway*, Carum Carui; *Sweet Marjoram*, Origanum majorana; *Summer Savory*, Satureja hortensis; *Sweet Basil*, Ocimum basilicum; and *Bush Basil*, O. minimum. These last, the basils, which are natives of the East, and in much request for their delicate flavour, are raised on hot-beds in spring, and transplanted with balls, into some warm situation. In Scotland, they are mostly treated as tender annuals, and are grown, under glazed frames, in flowerpots.

There are besides a few others, which, in each of the classes, more properly belong to the Dietetics, and the Materia Medica. The young green leaves of Prunus Laurocerasus (under the name of laurel), may properly enough be employed in garnishing; but they ought never to be used, as they too often are, for giving a nutty flavour, or for *greening* other articles; hydrocyanic acid being given out, and proving injurious, even in small quantities.

THE FLOWER GARDEN.

The cultivation of flowers, if not the most useful, is at least one of the most pleasing occupations of the horticulturist, and has generally shared largely in his attention. It is probable, that at first, flowers, as objects of curiosity, were confined to a few patches or borders in the garden, as is still the case in many old places; but in the progress of the art, and the diffusion of taste, separate departments were allotted to them under the name of Flower Gardens. After some general remarks on style and situation, we shall treat of the component parts of flower gardens, their various decorations, and of floriculture.

The designing of flower gardens unquestionably belongs to the fine arts, involving in it, the exercise of invention, taste, and foresight. Its principles are more vague and evanescent than those of any of the sister arts. The hand of the designer is not here guided by the imitation of Nature, for his work is wholly artificial in its arrangements and appliances; neither does utility come in, as in architecture, to supply a form and frame-work, which it is the artist's part to adorn. "As flower gardens," says Mr Loudon, the best authority on this topic, "are objects of pleasure, the principle which must serve as a guide in laying them out, must be taste. Now, in flower-gardens, as in other objects, there are different kinds of tastes; these embodied are called styles or characters; and the great art of the designer is, having fixed on a style, to follow it out unmixed with other styles, or with any deviation which would interfere with the kind of taste or impression which that style is calculated to produce. Style, therefore, is the leading principle in laying out flower gardens, as utility is in laying out the culinary garden. As objects of fancy and taste, the styles of flower gardens are various. The modern style is a collection of irregular groups and masses, placed about the house as a medium, uniting it with the open lawn. The ancient geometric style, in place of irregular groups, employed symmetrical forms; in France, adding statues and fountains; in Holland, cut trees and grassy slopes; and in Italy, stone walls, walled terraces, and flights of steps. In some situations these characteristics of parterres may, with propriety, be added to, or used instead of the modern sort, especially in flat situations; such as are inclosed by high walls; in towns, or where the principal building or object is in a style of architecture which will not render these appendages incongruous. There are other characters of gardens, such as the Chinese, which are not widely different from the modern; the Indian, which consists chiefly of walks under shade, in squares of grass; the Turkish, which abounds in shady retreats, boudoirs of roses and aromatic herbs; and the Spanish, which is distinguished by trellis work and fountains; but these gardens are not generally adapted to this climate, though, from contemplating and selecting what is beautiful or suitable in each, a style of decoration for the immediate vicinity of mansions, might be composed preferable to any thing now in use." It may, however, be remarked, that the flower garden properly so called, has generally been too much governed by the laws of landscape gardening, and these often ill-understood, and misapplied. In the days of "clipped hedges and pleached alleys," the parterres and flower-beds were of a description the most grotesque and intricate imaginable. At a subsequent period, when the natural and the picturesque became the objects of imitation in the park, there appeared the most extravagant attempts at wildness in the garden. The result has been unfortunate. It is not meant that when there are merely a few patches of flowers by way of foreground to the lawn, they should not be subordinated to the principles which regulate the more distant and bolder scenery; but wherever there is a flower garden of considerable magnitude, and in a separate situation, it should be constructed on principles of its own. In such a spot, the great object must be to exhibit to advantage the graceful forms and glorious hues of flowering plants and shrubs; and it is but seldom that mere elegancies in the forms of compartments, and other trickeries of human invention, can bear any comparison with these natural beauties. To express the peculiar nature of garden scenery, as distinct from the picturesque in landscape, Mr Loudon has invented the term *gardenesque;* and, whatever may be thought of the term itself, it is very desirable that the distinction should be preserved.

Two varieties of flower gardens have chiefly prevailed in Britain; one, in which the ground is turf, and the pattern, so to speak, is composed of a variety of figures cut out of the turf, and planted with flowers and shrubs; and another, when the flower-beds are separated by gravel walks, without being interspersed with grass at all. The choice of one or other of these varieties ought greatly to depend upon the situation. When the flower garden is to be seen from the windows, or any other elevated point of view, from which the whole or the greater part of the design may be perceived at once, perhaps the former should be preferred. Where the surface is irregular, and the situation more remote, and especially where the beauty of flowers is the chief object of contemplation, the choice should probably fall on the latter. This variety, too, seems preferable, on the principle of contrast, where there are large lawns in the outer grounds, in order that *kept* (or smoothly mown) grass may not be found every where.

Respecting the situation of the flower garden, no very precise directions can be given, as it must be influenced by the nature of the lawns, and of the site of the mansion to which it is attached. Generally speaking, it should not be at any great distance from the house; and in places where there is no distant view of importance, it may be constructed under the windows. In retired scenes, it is delightful to step out of the drawing-room into compartments of flowers, in the vicinity of a greenhouse or conservatory. On the other hand, when the park is spacious, and the prospects extensive and picturesque, it is perhaps better that the flower garden should be at some distance, say not more than a quarter of a mile, and out of sight of the house, but with an easy access in any sort of weather; an arrangement which would give an agreeable termination to a short walk, a desirable matter in most cases, for it has been often remarked that many parts of

Fl er
Ga en.

extensive grounds remain unvisited, because they afford no remarkable object to attract the attention.

The particular form of a flower garden is equally beyond the inculcation of specific rules. Indeed, it may be of any shape, and, except where the dimensions are extremely limited, the boundaries should not be continuously visible. The taste of the proprietor or designer, and the capabilities of the situation, must determine not only the external configuration, but also the arrangement of the interior parts. By judicious management, it may be made to pass through shrubbery, gradually assuming a more woodland character, and groups of trees, into the park on the one hand, and into the kitchen garden or orchard on the other. In most cases, even when it is in the vicinity of the mansion-house, the flower garden should be encircled with some sort of fence, in order to convey the idea of protection, as well as to furnish security to the vegetable inmates of the parterres, it being impossible to carry on floriculture to any great extent in open places which are accessible to hares and rabbits. In detached localities, the fences may be made sufficiently strong to preclude the intrusion of every species of vagrant; and these it is not difficult to mask with shrubs and trees. A north wall of moderate extent and moderate elevation, is often desirable, as affording space for ornamental climbers, and half-acclimatized exotics, and as forming a *point d'appui* for the conservatory and other botanical structures. Such a wall may be surmounted with urns and other architectural ornaments, and screened at some little distance behind by trees. The other fences may be of wire-work, generally called *invisible*, or of wooden rails, or of holly hedges with rails.

Formerly the flower-beds were made either circular, straight, or in curves, and were turned into knots, scrolls, volutes, and other compartments; and this taste prevailed, perhaps, in some measure from a desire on the part of the contrivers, to compensate by their ingenuity for the paucity of the ornamental plants which they then cultivated. Now that the riches of Flora have poured into our gardens, a simpler taste has obtained. Of the figures in fashion at present in the lawn-flower-garden, perhaps the kidney-shape and its varieties occur too frequently. It is needless as well as impossible to specify the numerous configurations of flower-plots, for they abound in kaleidoscopical variety. Good taste will suggest that those only should be associated which harmonize well together; and it is better to incur the hazard of an apparent monotony, than to excite wonder by incongruous combination. When the figures are separated by turf, it is necessary that the little lawns or glades should have a certain degree of breadth, as nothing has a worse effect than over-crowding. A multitude of little figures should also be avoided, as they produce what Mr Gilpin calls *spottiness*, and which, as he has correctly pointed out, is a grievous deformity. In this sort of flower garden, it is desirable that a gravel walk should skirt along at least one side of the principal figures; in our humid climate, the grass would otherwise render them inaccessible with comfort during a great part of the year. In those gardens in which turf is wholly or partly excluded, the compartments should be of a larger and more massive character. Narrow borders, bounded by parallel straight lines and concentric curves, should be avoided. The centres of the figures should be filled with tall-growing shrubs, and even with an occasional low evergreen tree, such as a yew or a holly. The walks, arranged in long concave curves, may communicate here and there with one another. A dial, a few seats and arbours, with an urn or two or a vase, may be introduced with good effect. It is to be regretted that few good specimens of this species of flower garden have hitherto been executed in Britain.

Amongst the accompaniments of the flower garden may be mentioned the Rock-work. This consists of variously grouped masses of large stones, generally such as are remarkable for being figured by water-wearing, or for containing petrifactions or impressions; and into the cavities between the stones, filled with earth, alpine or trailing plants are inserted. In proper situations, a small piece of water may be introduced, for the culture of aquatic plants. One of the walks is sometimes arched over with wire-work, and covered with ornamental climbing shrubs, forming a delightful promenade in the glowing days of summer. A separate compartment, generally of a regular figure, is set apart for roses, under the name of the Rosary. A moist or rather a shady border, with bog earth, is devoted to that class of shrubs, commonly, but not very accurately, designated "American plants." In extensive places, a separate "American Garden" is often formed, in a locality which, if not damp, has at least the command of water, occupying generally some warm corner of the park.

Flower
Garden.

Some writers have advocated the formation of Winter and Spring Gardens in separate localities; but we are not aware that their ideas have ever been embodied to any great extent. It is proposed that in the winter garden should be assembled all the most beautiful evergreen shrubs and plants, together with the few flowers that bloom during the winter months. The situation, it is recommended, should be well sheltered, and open only to the warm rays of the sun, which are peculiarly grateful in our cold winter seasons. However attractive this scheme may be in theory, it seems doubtful whether it would be very successful in execution. Masses of evergreens have a sombre and monotonous effect, even in winter, unless occasionally broken and varied by deciduous trees. The contrast of their leafless neighbours relieves the intenseness of their gloom, and sets off their brilliancy. Though a winter garden, the very name of which is chilling, is perhaps not very desirable by itself, the object to be attained in it should be kept in view in the formation of the park or flower garden. We can easily suppose a particular section of the latter to contain a predominance of evergreens, and to possess the principal characters of a Winter Garden, without the formality of its name and purpose. In the immense variety of situations, it is not difficult to imagine a sloping bank, for instance, facing the sun, with a long walk skirting its base, the lower side of which might be adorned with a border or narrow parterre planted with arbutus and periwinkle, whilst the slope is covered with the higher evergreens, and the summit of the acclivity is crowned with groups of deciduous trees, interrupted by a few straggling firs, through which the wind, unfelt below, might sigh its melancholy music. Again, the Spring Garden, which need not be of very great extent, may take refuge in the vicinity of the greenhouse or conservatory, with which it is naturally allied.

Soil.—A variety of soils is required in the flower garden, to suit the very different kinds of plants that fall to be cultivated. To florists' flowers particular compounds are assigned, and these shall be mentioned when treating of the flowers themselves. *American plants* require a peaty earth, varying from boggy peat to almost pure sand. Alluvial peat, that is, boggy earth which has been washed away and incorporated with white sand, is to be preferred: peat, cut from its natural bed and only partially decomposed, is of no value at all, or is positively prejudicial to plants. In collecting soil from the surface of a muir, it is proper to take no more than the upper turf or sod, with the peat adhering to it, and only from the driest parts of the muir, where, besides the common heath, fescue-grasses occur. Where this cannot be procured, a good substitute is found in vegetable mould, that is, decayed leaves swept from lawns or woods, and allowed to lie in heaps for a few years. For the general purposes of the flower garden, a light loamy soil is advantageous; and where the natural covering is thin, or requires making up, recourse should be had to the surface-earth of old pastures, which, especially when incumbent on trap-rocks, is found to be excellent. It is expedient to have a large mass of this material in the compost yard. The turf, and the surface-soil adhering to it, should be laid up in a rough state, in which way it is continually ameliorating by the decomposition of the vegetable matters, and the action of the air.

Garden Walks.—During the prevalence of the Dutch taste, grass-walks were common in our gardens; but, owing to their frequent humidity in our climate, they have in a great measure disappeared. Their disuse is perhaps to be regretted, as in some situations, particularly behind lengthened screens of trees, or in gardens from which grass has been in a great measure excluded, an example or two of them would be agreeable. It is justly observed by Sir William Temple, that "two things peculiar to us, and which contribute much to the beauty and elegance of our gardens, are the gravel of our walks, and the fineness and almost perpetual greenness of our turf;" and therefore no trouble should be spared in securing excellence in these respects. In old times grass walks were formed with much care. After the space which they were to occupy had been digged and levelled that it might subside equally, a thin layer of sand or poor earth was laid upon the surface, and over this a similar layer of good soil. This arrangement was to prevent excessive luxuriance in the grass. In selecting the seed, all annual, wiry, and coarse sorts of grass should be avoided. Perhaps a mixture of Roughish Meadow-grass (Poa trivialis), Sheep's Fescue-grass (Festuca duriuscula and Festuca ovina), and Crested Dogstail grass (Cynosurus cristatus), is about the best that could be selected. Poa nemoralis is well adapted for shaded situations.

Gravel-walks, in this department, are formed precisely in the same manner as those in the kitchen garden. It may, however, be remarked, that a multitude of gravel-walks, particularly when narrow, have a puny effect. All the principal lines should be broad enough to allow at least three persons to walk abreast; the others may be narrower. Much of the neatness of walks depends upon the material of which they are made. Gravel from an inland pit is to be preferred; though occasionally very excellent varieties are found upon the sea-coast. The gravel of Kensington and Blackheath has attained considerable celebrity; and is frequently employed in remote parts of the kingdom, the expense being lessened by its being conveyed to different sea-ports as ballast for ships. In summer a gravel-walk requires hoeing and raking from time to time, to clear it from weeds and tufts of grass. After this operation, or even after a simple sweeping, it is rolled down with a hand-roller; and this is repeated as often as the surface is ruffled. Nothing contributes more than frequent rolling to the elegance and convenience of garden walks.

Edgings.—Walks are generally separated from the borders and parterres by a variety of plants planted closely in line. By far the best edging is afforded by the Dwarf Dutch Box (Buxus sempervirens var). It is extremely neat, and, when annually clipped, will remain in good order for many years. It may be planted at any season, except when in full growth or in mid-winter. Excellent edgings are also formed by Sea Pink (Statice armeria) and Double Daisy (Bellis perennis). Dwarf Gentian (Gentiana acaulis) and London Pride (Saxifraga umbrosa) are also sometimes used. Indeed, any low-growing herbaceous plant, susceptible of minute division, is fitted for an edging. Among the great variety occasionally employed for this purpose may be mentioned, the Pansy (Viola tricolor), the Dwarf Bell-flower (Campanula pumila), the Cowslip, Polyanthus, Auricula, Hepatica, Veronica fruticulosa, and Erica carnea. Edgings may also be formed of spars of wood, narrow pieces of sandstone flag, or even of slight bars of cast iron. In shrubberies and large flower-plots, verges of grass-turf, about a foot in breadth, make a very handsome border to walks. These should not be allowed to rise high above the gravel: an inch and a half may be assigned as the limit they should not exceed. The grass is kept short by repeated mowings, and the edges are defined by clipping with shears, or cutting with a paring iron.

Shrubs.—Much of the beauty of the pleasure garden depends upon the proper selection and disposition of ornamental trees and shrubs; and it is to be regretted that this department of the art has often been greatly neglected. In many gardens we still find only a few evergreens, and a parcel of rugged deciduous species, introduced probably before the age of Miller. No wonder is it, therefore, that we sometimes hear of the insipid scenes of the shrubbery. Nevertheless, shrubs are highly elegant in themselves, and they afford a most efficient means of diversifying garden scenery. Of the many beautiful species now to be had in Britain, and affording the materials of exquisite decoration, we can mention only a few. For extensive lists and for much general information, we may once more refer to the work of Mr Loudon.

Of Evergreens, besides the Common Laurel (Prunus Laurocerasus) and the Portugal Laurel (P. Lusitanica), we may notice the American Arborvitæ (Thuja occidentalis), as adapted to large masses of shrubs; and the Chinese Arborvitæ (T. orientalis), whose size and mode of growth fit it for smaller compartments. The different varieties of Rhamnus Alaternus, and the species of Phillyrea and Juniperus, have long and deservedly been favourite evergreens. The Sweet Bay (Laurus nobilis), in favourable situations, rises into a handsome shrub or low tree, and may convey to the student of the classics an idea of the Delphic laurel. The Strawberry tree (Arbutus Unedo), a native of Ireland as well as of the south of Europe, will always find a place as one of the most elegant of plants, equally beautiful as regards foliage, flower, and fruit: nor should its countryman, the Irish Yew, ascending like the pillared cypress, be forgotten. The Cypress itself, though rather a denizen of the park, may be sparingly introduced. The Laurustinus (Viburnum Tinus), with blossoms approaching the snow in whiteness, enlivens the winter season, when nothing else is in flower in the shrubbery. The Swedish and Irish Junipers deserve a place. Different species of Daphne will not be forgotten; it may be sufficient to enumerate pontica, collina, Cneorum, and hybrida. As extremely low evergreens, we may mention Gualtheria procumbens and Shallon, Polygala Chamæbuxus, and Astragalus Tragacantha; but these would probably be better placed among what are popularly called American plants. Of the more tender evergreens, we should name the Andrachne (Arbutus Andrachne), a beautiful shrub, but liable to be injured by severe frosts. The Broad-leaved Myrtle (Myrtus Romana), in warm places, and with the aid of a covering in the depth of winter, may be made to clothe the walls with its brilliant verdure for eight months in the year, and with its white flowers for some weeks in the end of summer. Aucuba Japonica, and Buxus Balearicus, are handsome shrubs, of a somewhat stronger constitution: the former is very ornamental in dull shady places, where no other shrub will grow. The beautiful tribes of Cistus and Helianthemum, some of which are quite hardy, are admirable for adorning sloping banks.

Amongst the shrubs that require a peaty soil, or at least a damp and shady situation, the splendid genus Rhododendron holds the principal place. Of the larger species may be mentioned R. Ponticum, Catawbiense, and maximum, with their many beautiful varieties. In early spring, R. Däuricum expands its blossoms among the first of flowering shrubs. Nor should we overlook R. punctatum, hirsutum, ferrugineum, and Chamæcistus, of humbler growth, but not inferior in beauty. With these the closely cognate genus of Azalea, with its multitudinous species and varieties, disputes the palm of elegance. The pale and drooping Andromedas are scarcely of inferior interest. The hardy Heaths, particularly Erica carnea, tetralix, and stricta, Menziesia polifolia and cœrulea, and the Canadian Rhodora, combine to bring up the rear of this department of Flora's train.

The deciduous flowering shrubs are too much neglected in many gardens. They are seldom well managed, either in point of arrangement or in the evolution, by pruning, of picturesque effect. Very often they are huddled together promiscuously, and grow up into the shape of huge sheaves of rushes. With judicious management, there is not a finer object in the vegetable kingdom than the common Lilac (Syringa vulgaris), or the hybrid Varin (S. Rathomagensis). Even the old Guelder-Rose (Viburnum Opulus) is worthy of the poet's eulogy; the "scentless rose," which he describes as "tall,"

> "And throwing up into the darkest gloom,
> Of neighbouring cypress, or more sable yew,
> Her silver globes, light as the foamy surf
> That the wind severs from the broken wave."

It would lead us into disproportioned detail to specify a tithe of those shewy shrubs which should be dear to every floriculturist. Suffice it to name Ribes sanguineum, Daphne mezereum, Spartium of many species, Cytisus, Amygdalus, and Pyrus. The Ribes speciosum, or Fuchsia-flowered gooseberry, seems to require the protection of a wall, but deserves it. The fine suffruticose plant Pæonia Moutan, requires the most sheltered position in the shrubbery, where, in May and June, its flowers excel all others in magnificence. From such a list as that published by Mr Loudon, any one might form such a collection as, when properly arranged, would produce all the variety and beauty expected from the shrubbery.

There are many fine climbing shrubs, such as the species of Clematis, and of Lonicera or Honeysuckle. Others, though not precisely of this class, are much beholden to the shelter of a wall, such as the beautiful Magnolia conspicua, and Edwardsia tetraptera and microphylla. Among those of recent introduction, may be noticed Glycine Sinensis and Eccremocarpus scaber. The numerous species or varieties of Fuchsia, when planted against a wall, or even in the open ground, and shaded with an occasional covering in winter, convey to us a better idea of the riches of Chilian vegetation, than when they are confined to the shelves of the greenhouse. Many roses are also well adapted for walls, such as the varieties of Noisette, Boursault, and the different species from China.

A separate compartment, called the Rosary, is generally devoted to the cultivation of roses. It is often of an oval form, with concentric beds, and narrow intervening walks of grass or gravel, but it may assume any configuration which is suited to display this favourite plant. Of the thousand varieties of roses which exist in the nurseries, we pretend not to give any selection. It may, however, be remarked, that in planting the Rosary, care should be taken to classify the sorts according to the sizes and affinities, otherwise the effect will be much impaired. The climbing sorts may be advantageously introduced, being trained to pillar-like trellises. When the rosary is extensive, it is judicious to intersperse some of the most showy hollyhocks; for thus the beauty of the quarter is maintained in the later months of autumn, when the roses are chiefly past. Of late years, quantities of standard roses have been imported from the Continent. These are the finer sorts, budded on tall stocks of the wild species, such as R. villosa and canina. They are well adapted to stand singly on the little lawns in flower-gardens, or to break the uniformity of low flower borders.

All shrubs nearly may be propagated by layers, some by budding or grafting, many by separating the roots. In planting, shrubs may be arranged either singly or in masses: the latter method is perhaps the most efficient in the production of effect, but it should not be very servilely adhered to, as it is apt to beget monotony. Some kinds should never appear in masses: The white Portugal broom, for instance, when so arranged, gives a limy tint to a garden. Perhaps it is better that groups should contain a predominance of one shrub, set off by a few others of a contrasting figure or colour, than that they should be entirely homogeneous.

Herbaceous Plants.—Common perennial flowers, whether strictly herbaceous or bulbous, afford the principal materials for floral decoration. Botany supplies, as it were, the colours for the picture, and gardening grinds and prepares them for use. The painting is continually varying, and new shades are arriving and departing in succession. The least consideration of the subject will suggest the rule, that in planting flowers they should be arranged according to their stature, otherwise many of the most beautiful little flowers would be lost among their taller compeers. The lowest plants should therefore stand next the margin of the border or parterre, and they should increase in height as they go back. To produce a full shew, a profusion, just not amounting to crowding, is requisite. The flower-plots should present a regular bank of foliage and blossom, rising gradually from the front; but as this might convey an idea of too great precision, a few *staring* plants, on the same principle as those employed in greenhouses, should be thinly scattered over the surface. These may be shrubs, or any tall showy plant, such as Bocconia cordata, Papaver bracteatum, Gladiolus Byzantinus, or Lilium candidum. The management of colour is more difficult. When the length of the flowering season is considered, it will be obvious that it is impossible to keep up the show of a single border or plot for six months together, and consequently that much of the labour employed in mixing colours is misspent, since plants, as they are commonly arranged, come dropping into flower one after another; and even where a certain number are in bloom at the same time, they necessarily stand apart, and so the effects of contrast, which can be perceived only among adjacent objects, are entirely lost. To obviate this defect, it has been recommended that ornamental plants should be formed into four or five separate suites of flowering, to be distributed over the garden. Not to mention the more vernal flowers, the first might contain the flora of May; the second that of June; the third that of July; and the fourth the tribes of August and the following months. These plants should be kept in separate compartments, arranged either singly or in masses; but the compartments themselves should be so intermingled, as that no particular class should be entirely absent from any one quarter of the garden. The May parterres should, however, chiefly occur in the vicinity of the greenhouse or conservatory, or, when these are absent, in a warm sunny situation. The flowerings of June and July, as being highly shewy, should occupy the most conspicuous parts of the garden. The autumnal perennials, not being so imposing, may retire into the more secluded situations, as they are supplanted by the superior brilliancy of the annuals, which fill the vacant beds of florists' flowers, or are scattered over the faded clumps of May and June.

Before attempting to plant, the floriculturist would do well to construct tables or lists of flowers, specifying their respective times of flowering, their colours, and altitudes. These tables, when skilfully used, would prevent mistakes, produce a greater facility of execution, and put the colours nearly as much under control as they are on the painter's pallet. To diversify properly and mingle well together the reds, whites, purples, yellows, and blues, with all their

Flower Garden.

intervening shades, requires considerable taste and powers of conception; but if success is not attained in the first attempt, inaccuracies should be noted, and rectified at the proper time next season. Certain series of colours have been given, but these it is needless to mention, as it is quite immaterial whether the first flower in a row be red or white. The principal object is to preserve an agreeable contrast; and as at particular seasons a monotony of tint prevails, it is useful at such times to be in possession of some strong glaring colours. White, for instance, should be much employed in July, to break the duller blues and purples which then preponderate. The orange lily, too, is very effective at that season. On the other hand, yellows are superabundant in autumn, and therefore reds and blues should then be sought for.

Besides mere vividness of colour and elegance of form, there are other qualities which render plants desirable in the flower-garden. Whoever has visited a botanic garden, must have been sensible of an interest excited by the curious structure or by the scarcity of some plants. Even quaintness of form is deserving of attention. The writer of this article has seen Allium fistulosum (the common Welsh onion) making a conspicuous figure in a flower-garden; and he remembers well a plant of sea-kale (Crambe maritima), which the good taste of the owner had introduced into the parterre, to the great disturbance of the ideas of the gardener. At the same time, it must be admitted that such expedients should be employed with reserve. No handsome plant should be rejected because it is common, nor any inconspicuous weed preserved merely because it is scarce. The flower-gardener should have a small nursery for the propagation of finer plants, to be transferred into the borders as often as is required.

We shall enumerate merely the names of a few of the most shewy flowers, adapted to the British flower-garden.

Vernal Herbaceous Plants.—Helleborus niger, lividus; Erianthus hyemalis; Hepatica triloba var.; Primula vulgaris var., veris, elatior, marginata, helvetica, nivalis, viscosa, integrifolia, cortusoides; Cortusa Matthioli; Soldanella alpina, Clusii; Viola odorata, tricolor, biflora, altaica; Dodecatheon Meadia vars.; Orobus vernus; Adonis vernalis; Omphalodes verna; Corydalis lutea, longiflora; Sanguinaria canadensis; Iris pumila; Anemone apennina, Halleri, pulsatilla.

Vernal Bulbous Plants.—Galanthus nivalis; Leucoium vernum; Crocus, species; Cyclamen coum, vernum; Corydalis bulbosa; Erythronium Dens canis; Narcissus Pseudo-narcissus, moschatus, odorus, Jonquilla, &c.; Fritillaria imperialis, meleagris, persica; Gagea lutea; Tulipa sylvestris; Iris persica; Trillium grandiflorum, &c.; Scilla verna, præcox, bifolia, sibirica.

Herbaceous Plants flowering in May. Anemone narcissiflora, sylvestris, dichotoma; Primula farinosa, scotica; Convallaria majalis; Uvularia grandiflora, perfoliata; Phlox divaricata, subulata, setacea, &c.; Asphodelus luteus, ramosus; Draba Aizoïdes; Viola cornuta, obliqua; Gentiana verna, acaulis; Lupinus polyphyllus; Gaillardia bicolor; Iris florentina, cristata, &c.—*Bulbs*: Leucoium æstivum, Scilla non-scripta, italica, &c. Hyacinthus monstrosus; Muscari moschatum, botryoides, comosum; Narcissus Bulbocodium, poëticus, &c.

June—Herbaceous Plants. Pæonia officinalis, albiflora, corallina, Humii, &c.; Dianthus, species; Geranium sanguineum, Lancastriense, Wallichianum, striatum, &c.; Monarda didyma, Kalmiana; Papaver bracteatum; Saxifraga, species; Spiræa, species; Mimulus luteus, moschatus; Trollius Americanus, europæus; Lysimachia verticillata; Veronica latifolia, &c.; Geum coccineum; Aconitum napellus, &c.; Potentilla nepalensis, &c.—*Bulbs*: Allium Moly, Gladiolus byzantinus, communis; Lilium Pomponium, bulbiferum, aurantiacum, monadelphum, penduliflorum, concolor, &c.; Iris Xiphium, Xiphioides, &c.

Flow Gard

July—Herbaceous Plants: Phlox intermedia, and many other species of that fine genus; Pentstemon, numerous species; Œnothera, various species; Campanula persicifolia, &c.; Asclepias amœna, syriaca; Iris fulva, pallida, variegata; Gentiana lutea, asclepiadea, cruciata, septemfida, &c.; Chelone obliqua, barbata, Lyoni.—*Bulbs:* Lilium martagon, canadense, tigrinum, superbum, &c.; Gladiolus cardinalis, Tigridia pavonia, Commelina cœlestis, Cyclamen hederæfolium.

Autumnal Herbaceous Plants: Phlox decussata, pyramidalis, tardiflora, &c.; Lobelia cardinalis, fulgens, splendens, &c.; Aster sibiricus, amellus, pulcher, &c.; Eschscholtzia californica; Solidago, several species; Aconitum japonicum, volubile, variegatum; Gentiana Saponaria; Pentstemon, several species.—*Bulbs:* Colchicum autumnale; Crocus nudiflorus, serotinus; Tritona pallida, media.

It is with regret that we thus confine ourselves to a dry list of border flowers; but to do them any thing like justice, would require many pages. Within the last few years great accessions have been made to our stores. The Lupines and Pentstemons from the Columbia River, the Verbenas and Calceolarias from South America, and the Potentillas and Geraniums from Nepal, have in a great measure changed the face of our flower gardens. While our riches have increased, the difficulty, as well as the necessity, of making a selection have increased also.

Most herbaceous perennial plants are propagated by parting the roots, or by cuttings; but some most conveniently by the sowing of seed.

Biennial Plants. Plants whose existence is limited to two years, in the latter of which they flower and then decay, are called biennials. Many of them possess considerable beauty; and by their easy propagation, and rapid growth, they afford a ready means of decorating borders. The following may be considered most worthy of notice: Agrostemma coronaria; Antirrhinum majus; Hedysarum coronarium; Lunaria biennis; Campanula media; Œnothera sinuata, biennis; Verbascum formosum, Hesperis matronalis, Scabiosa atropurpurea, Mathiola simplicicaulis. When a very desirable variety is procured, such as the striped Antirrhinum majus, attention should be paid to the striking of cuttings during the summer, as the only means of continuance.

Biennials are sown in beds in the end of spring, and are generally transplanted in the course of the autumn, into the places where they are intended to stand, that they may be confirmed before winter, and shoot up readily into flower in the following summer.

Annual Plants.—Many of the annuals species, though of fugitive duration, are possessed of much beauty of hue and elegance of form. They are further valuable from their pliability, so to speak, and the promptitude with which they may be used. They are besides of easy culture, many requiring nothing more than to have the seeds sown in the spot where they are to grow. Annuals may be divided into three classes, the *hardy*, the *half-hardy*, and the *tender*. The first class, as stated above, are sown at once in the ground which they are to occupy; the *half-hardy* succeed best when aided at first by a slight hot-bed, and then transplanted into the open air; the tender are kept in pots, and treated as greenhouse or stove-plants, to which departments they properly belong. It is scarcely necessary to remark that the *hardy* and *half hardy* sorts may be grown either in patches or in beds, and are subjected to all the rules which regulate the disposition of common border flowers.

Hardy Annuals.—Adonis autumnalis; Iberis umbellata; Knautia orientalis; Alyssum, several species; Linaria, various species; Delphinium Ajacis, consolida; Silene Armeria; Campanula speculum, Lorii; Lavatera trimestris; Malope trifida; Hibiscus trionum, bifrons; Nolana, various species; Papaver somniferum, numerous varieties; P. Rhœas, varieties; Gilia capitata, tricolor; Collinsia grandiflora; Kaulfussia amelloides; Clarkia pulchella, elegans; Œnothera rosea, rosea-alba, tenella, Lindleyana, Romanzovii; Rudbeckia amplexicaulis; Senecio elegans; Mathiola annua; Lupinus, several species.

Half-hardy Annuals.—Callistemma hortense; Lopezia racemosa, Tagetes patula, erecta, racemosa, &c.; Zinnia elegans, pauciflora; Xeranthemum annuum, Helichrysum fulgidum, Chrysanthemum carinatum; Amaranthus caudatus; Schizanthus pinnatus, porrigens, Grahami, Hookeri; Salpiglossis atro-purpurea, straminea; Petunia nyctaginiflora; Mirabilis Jalapa.

Tender Annuals.—Impatiens Balsamina, Browallia elata, Celosia cristata, Gomphræna globosa; Solanum melongena; Mesembryanthemum crystallinum.

We have been able to enumerate only a small selection of species, out of a multitude which is continually receiving accessions. Many of the sorts mentioned above have been introduced during the last ten or fifteen years; and we doubt not that, in an equal period from the present, many more will come into notice.

Before leaving this part of the subject, it may be proper to mention, that it is now the practice of some florists to grow and treat as annuals, or rather as biennials, great quantities of the more hardy Pelargonia, Verbenæ, Salviæ, Fuschiæ, Hemimeris, and other genera. Mr James Smith at Hopetoun House, every season propagates, by cuttings or seeds, several hundreds of these plants. Grown in moderate-sized pots, they are kept in frames or cold vineries during winter. About the end of May, or as soon as there is no longer any apprehension of injury from frost, the plants are taken out of the pots and plunged into the open ground, in any warm sunny spot or clump in the flower garden. If the stems are long or naked, they are pegged to the earth. Towards the middle of July they begin to grow vigorously, and in August or September present, in luxuriance, at least, if not in magnitude, a better representation of their native vegetation than we see elsewhere in our gardens. Upon the approach of frost, they are, with the exception of the Fuschias, left to their fate, as it is easier to propagate new ones than to preserve the old. These plants, with the fine new annuals, and the gorgeous Dahlias, give a splendour to the autumnal flower garden which in former times it did not possess.

Florists' Flowers.—This technical appellation has been restricted to certain flowers, which have been especial favourites with florists, and have consequently received a large share of their attention. Though possessed of great individual beauty, few of them are calculated to make a shew at a distance, and the arrangements requisite for their culture do not harmonize well with the general disposition of a flower garden. It is, therefore, desirable, particularly when considerable refinement is aimed at, that a separate garden, or a separate section of the garden, should be set apart for their culture. The more robust or less valuable varieties, however, which are often as shewy as the most esteemed, may be introduced into the general parterres. We shall notice the most considerable, in the order in which they naturally attract attention.

The Hyacinth, Hyacinthus orientalis, one of the most beautiful and fragrant of the spring flowers, is a native of the Levant, where it occurs abundantly, in form not unlike our common harebell. It has long been a favourite in the East: but has been brought to its present artificial perfection in Holland, chiefly since the beginning of last century. Many years ago it was successfully grown in the vicinity of Edinburgh, by Justice, one of the most ingenious horticulturists of his time: but it must be confessed that, in the culture of this flower, the British florists have never attained to the eminence of the Dutch, principally, however, as is alleged by some, from want of attention and pains-taking. According to Miller, the catalogues of the Haarlem florists used to enumerate 2000 sorts, some of which sold as high as L. 200 a bulb: they are now less numerous, and much less expensive.

Hyacinths are either single, semidouble or double, and exhibit a great variety of tint. In a fine flower the stalk should be tall, strong, and upright; the blossoms numerous, large, and suspended in a horizontal direction; the whole flower having a compact pyramidal form, with the uppermost blossom quite erect; the plain colour should be clear and bright; and strong colours are preferable to pale; when colours are mixed they should blend with elegance.

The hyacinth delights in a rich light sandy soil; and it is chiefly owing to the want of these qualities in his composts, that the British florist fails in the growth of this beautiful plant. The Dutch compost, as given by the Hon. and Rev. Mr Herbert in the *London Hortic. Transactions* vol. iv., is the following: One-third coarse sea or river sand; one-third rotten cow-dung without litter; and one-third leaf mould. The natural soil is removed at least two feet deep, and the vacant space filled up with compost, previously prepared and well mixed. These materials retain their qualities for six or seven years, but the Dutch do not plant hyacinths upon the same place for two years successively. In the alternate years they plant it with narcissus or crocus. We may mention that, in the finest bed of hyacinths which we have seen in Scotland, a considerable portion of the soil was composed of *sleetch*, a sort of sandy and marly deposition from the ooze on the shores of the Forth.

According to Mr Main (*Villa and Cottage Florists' Directory*, p. 84.) St Crispin's day, the 25th of October, is the best time to plant the bulbs. They are arranged in rows, eight inches asunder, there being four rows in each bed; or, if more convenient, they may be placed in rows across the bed. The bulbs are sunk about three or four inches deep, and it is recommended to put a small quantity of clean sand below and all around them. As the roots are liable to be injured by frost, it is usual to cover the beds with decayed tan-bark, with litter or with awnings. The first may be considered the neatest during winter, but an awning is nearly indispensable in spring when the lingering colds prove exceedingly hurtful to the young flower-stems. The awning may be made of coarse sheeting or duck. As the flower-stems appear, they are tied to little rods, to keep them upright and preserve them from accident. In order to perfect the colours, the rays of the sun are admitted in the morning or in the evening, but the glare of mid-day and the cold of the night, are both excluded. When the season of blossom is over the awning is removed, or only replaced to keep off heavy rains. Much of the success, in the culture of this flower, depends on the subsequent management of the bulbs. It is the practice in Holland, about a month after the bloom, or when the tips of the leaves assume a withered appearance, to take up the roots, and, cutting off the stem and the foliage within half an inch of the bulb, but leaving the fibres, to lay the bulbs sideways on the ground, covering them with half an inch of dry earth. After three weeks, they are again taken up, cleaned, and removed to the store-room. In this country it is more common to allow them to stand till the leaves be withered, and then to take them up at once. In the store-room the roots should be kept dry, well-aired, and apart from each other.

Where forcing is practised, a few hyacinths may be forced in deep flower-pots filled with light earth, and, when coming into flower, transferred to the greenhouse, which they enliven at the deadest season of the year. In chambers, they are grown in water-glasses made for the purpose; or, with still greater advantage, in boxes filled with damp hypnum moss.

New varieties of hyacinths are procured by sowing the seed; but this is a tedious process, and seldom followed in this country. The established sorts are propagated by offsets or small bulbs, which form at the base of the parent bulb. Almost all the hyacinths cultivated in this country are imported from Holland, and the quantity of roots annually introduced must be very considerable.

The *Tulip*, Tulipa Gesneriana, is a native of the East, whence it was introduced in Europe about the middle of the 16th century. Gaudy as it is, it has no proper corolla, but only a calyx of six coloured sepals. About the year 1635 the culture of the tulip was very engrossing; and, indeed, the rage for possessing rare sorts had become so great in Holland, as to give rise to a strange species of gambling, known to the collectors of literary and scientific anecdotes by the name of Tulipo-mania, which has tended to bring unmerited discredit on this fine flower. At present the finer tulips are mostly of moderate price, and, though not to be met with in every garden, have yet some ardent cultivators.

There are some varieties, such as the early Duc Van Thol, the Clarimond, the Parrots, and the Double Tulips, which belong, properly speaking, to the general cultivator. In this country, the florists' tulips are arranged under four classes. 1. The *Bizarres*, which have a yellow ground marked with purple or scarlet. 2. The *Byblœmens*, with a white ground marked with violet or purple. 3. The *Roses*, with a white ground marked with rose-colour. 4. The *Self* or *Plain-coloured* tulips, which are of one uniform colour, and are chiefly valued as breeders. The Byblœmen class includes most of those tulips which are held in highest esteem in this country.

The properties of a fine late tulip, as specified by Mr Hogg, are the following, somewhat abridged. The stem should be strong, erect, thirty inches high: the flower large, of six petals (sepals), which should proceed almost horizontally at first, and, turning up, should form an almost perfect cup, with a round bottom, rather widest at top. The three exterior petals should be rather larger than the three interior ones: the limbs of the petals should be rounded, and freed from every species of serrature. The ground colour of the flower at the bottom should be clear white or yellow; and the various rich-coloured stripes, which are the principal ornament of a fine tulip, should be regular, bold, and distinct at the margin, and terminate in fine broken points, elegantly feathered or pencilled. There are other refinements upon which florists are not quite agreed: and it must be confessed, that their standard of excellence is somewhat factitious; for, to an uninstructed eye, though practised in the contemplation of other sorts of beauty, a tulip, which by them is looked upon as worthless, will often appear as fine as the choicest variety in the select bed.

Tulips prosper in a light sandy soil, richly manured with well rotted cow dung. Twenty inches depth of soil should be removed, and the vacant space filled up with compost. Some put alternate layers of light soil and cow dung. The bed should be filled up with compost about the middle of October, and in a fortnight, when the soil has subsided, the bulbs are planted in rows, distant eight or nine inches, and at the depth of about three inches. A little clean sand may be put around the bulbs. After planting, the bed may be covered over with tan, or with a hooped awning, as in the case of hyacinths. In spring, it is necessary to shield the leaves and flower-stalks from frost, and also from heavy rains; and, when in bloom, the flowers must be sheltered from the sun's rays, by which they are speedily injured. After the sepals have fallen, the seed-vessels are broken off close by the stem, to prevent the plant from exhausting itself in perfecting seed, and to direct its energies to the forming of the new bulb. When the leaves have withered, the bulbs are taken up, dried, and stored until the planting season come round.

Tulips are readily propagated by offsets, which are taken off from the parent bulbs, and nursed in separate beds till they be full grown. New varieties are raised from seed; they are from five to seven years old before they flower, and, if raised from promiscuous seed, they often turn out worthless. Early in the 18th century, the distinguished Scottish cultivator, Sir James Justice (already mentioned as a most successful cultivator of hyacinths), was eminently successful in raising fine seedling tulips; and some skilful florists of our own day, such as Mr Strong of Brook Green, and Mr Oliver of Edinburgh, succeed in breaking their seedlings into colours equal to the finest byblœmens of Holland. They save the seeds from the first-rate sorts, the stigma of the intended parent flower having been fertilized with the pollen of some other fine variety. Seedling tulips, it may be remarked, present this anomaly for the first two or three years, that they form their new bulbs several inches below the old ones, so that an inexperienced cultivator is sometimes apt to miss them at the time of lifting.

The *Ranunculus* (R. Asiaticus) is, like many of the other florist's flowers, a native of the Levant, where it is a favourite of the Turks. It has sported into innumerable varieties, and those now in cultivation in this country are mostly of British origin. The plant is of small stature, furnished with decomposite leaves, and rising from a root formed by a bundle of little tubers.

According to the canons of floral criticism, the properties of a fine double ranunculus are the following: The stem should be strong, straight, and from eight to ten inches high, supporting a large well-formed blossom at least two inches in diameter, consisting of numerous petals, the largest at the outside, and gradually diminishing in size as they approach the centre of the flower, which should be well filled up with them. The blossom should be of a hemispherical form; its component petals imbricated neither too closely nor too much separated, and having rather a perpendicular than a horizontal direction. The petals should be broad, and have perfectly entire well-rounded edges; their colours should be dark, clear, rich or brilliant, either consisting of one colour throughout, or be otherwise variously diversified on an ash, white, sulphur or fire-coloured ground, or regularly striped, spotted, or mottled in an elegant manner.

The ranunculus requires a stronger and moister soil than most other flowers. Maddock prefers a fresh, strong, rich loam. Hogg recommends a fresh loam, with a considerable portion of rotted cow or horse dung. The Rev. Mr Williamson (Hort. Trans. vol. iv.) uses a stiff clay loam, with a fourth of rotten dung. "The bed should be dug from eighteen inches to two feet deep, and not raised more than four inches above the level of the walks, to preserve the moisture more effectually: at about five inches below the surface should be placed a stratum of two-year-old rotten cow dung, mixed with earth, six or eight inches thick; but the earth above this stratum, where the roots are to be placed, should be perfectly free from dung, which would prove injurious if nearer. The fibres will draw sufficient nourishment at the depth above mentioned; but if the dung were placed deeper, it would not receive so much advantage from the action of the air." Other florists have recommended to put the manure at least two feet and a half below the surface of the earth. The principal object, however, is to maintain throughout the bed a genial moisture; and this is to be done by avoiding all hot gravelly earths, and particularly soils that are apt to cake. The tubers are planted late in autumn or early in spring, in rows five or six inches apart, and three or four inches separate in the rows. They should be so close that the foliage shall cover the surface of the bed, for in this way a salutary degree of shade and moisture is preserved. The autumn planted roots must be sheltered from frost by old tan or hooped mattings. When in flower, the plants are covered with an awning. When the leaves wither, the roots are taken up, dried, and stored.

Scarcely any florists' flower is more readily propagated from seed, or sooner repays the care of the cultivator. The seed is obtained from semi-double sorts, which are often of themselves very beautiful flowers. It is generally sown in boxes in autumn or spring. We have often seen it committed with success to the open ground. The young plants thus raised flower, often in the second, and always in the third year.

The *Anemone* of the flower garden includes two species, Anemone coronaria, a native of the Levant, and A. hortensis, a native of Italy. These have long shared the attention of the florist, and in his arrangements have generally been associated with the ranunculus, resembling it in its natural affinities and mode of culture. The single and semi-double flowers are considered nearly as fine as the double ones. The sorts are numerous, but at present are seldom distinguished by names. In a fine double anemone, the stem should be strong, erect, and not less than nine inches high. The flower should be at least two and a half inches in diameter, consisting of an exterior row of large well rounded petals, in the form of a broad shallow cup, the interior part of which should contain a number of small petals, mixed with stamens, imbricating each other. The colours should be clear and distinct, when diversified in the same flower, or striking and brilliant, when there is only one tint.

The soil and culture are so nearly the same as in the ranunculus, that it is needless to specify them. The plant continues longer in flower, and the leaves often remain so long green, that it is difficult to find a period of inaction in which to take up the roots. It has been recommended, that as soon as the bloom is over, the bed should be screened from rain by mattings until the leaves wither. As the roots are rather brittle, they require considerable care in handling. Anemones are easily raised from the seed. A bed of single anemones, it may be remarked, is a valuable addition to a flower garden, as it affords, in a warm situation, an abundance of handsome and often brilliant spring flowers, almost as early as the snowdrop or crocus.

The *Narcissus* is an extensive genus, including a great many interesting species and varieties. It belongs, however, rather to the botanico-florist than to the florist proper; but as it contains many plants of great elegance, it ought to receive more general attention. The Polyanthus Narcissus (N. Tazetta) affords the varieties which are chiefly cultivated by florists. These prosper in a rich light soil, containing a little dung. The roots should not be stirred more frequently than once in three years; and this remark applies also to Narcissus Jonquilla and odorus, the small and large jonquil, of which fragrant plants there should be beds in every flower garden. N. Tazetta, like the hyacinth, may also be grown either in pots or in water-glasses.

Iris. The species which peculiarly appertain to the florist are, I. Xiphium and Xiphioides, of both of which there are many beautiful varieties. They are of easy culture, succeeding in almost any kind of soil, and requiring to be moved only once in three or four years. The roots are not improved by being kept out of the ground; and perhaps the best method is, upon taking them up and freeing them from their shaggy skins, to replant them immediately.

Besides these, may be mentioned the Persian Iris (I. Persica), a low bulbous-rooted plant, with delicate blue or violet coloured flowers, and a high degree of fragrance. It has long been cultivated by the Dutch, from whom bulbs are annually procured. It is grown in water, or in pots of nearly pure sand. When planted out, it requires to be guarded from frosts and rain. The Snake's-head Iris (I. tuberosa, *Bot. Mag.*) is also a fragrant species, and is more hardy than the preceding. Mr Denson, who has been very successful in the culture of this plant, recommends, in *Gard. Mag.* vol. viii., that it should be allowed to stand two or three years in succession on the same spot; when, "in July, take it up and divide the tubers, planting them soon as dug up, six inches deep in a compost formed of half friable mould, and half leaf mould, or old hot-bed dung, rotted to the consistence of soil. Let the situation be a dry bed or border, at the base of a wall, with a southern aspect, and plant the tubers close to the wall, or only a few inches from it." The Chalcedonian Iris (I. susiana), is the most magnificent species of the genus, and is well worth the labour of the cultivator. Its little stalk, a few inches high, is surmounted by a splendid corolla, the petals of which are nearly as broad as the hand, and are of a purple or black ground, striped with white. It loves a loamy soil, and a sunny exposure, and must be guarded from moisture and frosts in winter. For these three species Mr Loudon recommends the protection of a frame.

There are many other species which are worthy of a place in a select flower garden, and when well grouped in a peaty earth, form an agreeable appendage to a parterre. Of these we may mention the low creeping I. cristata and pumila, the more aspiring prismatica, flexuosa, virginica, sordida, variegata and Swertii, the taller Sibirica, triflora and ochroleuca, the broad leaved Florentina, Germanica and sambucina, and the stately pallida, which, for simple elegance, is not outshone by any of its compeers. This beautiful family is much beholden to David Falconer, Esq. of Carlowrie, who has introduced some of its most interesting members to the horticultural world in Scotland.

The *Lily.* Of the genus Lilium there are many species, some of which have not been exhibited to the extent of their capabilities in the flower garden. The old white Lily (L. candidum, L.) after supplying the poets with so much imagery, has retired into the modest station of a common border flower. The flaunting Orange-Lily (L. bulbiferum) may be allowed, if it pleases, to follow its example. L. martagon may occupy the same place. The scarlet Turk's Cap (L. Chalcedonicum) is worthy of more care, as being more beautiful and more tender. It does not relish being disturbed, and it dislikes peat. On the contrary, the splendid Tiger Lily (L. tigrinum), which propagates rapidly by axillary bulbs, succeeds best in peaty soil. The same remark applies to the rarer L. canadense, and superbum (magnificent species) as well as to L. concolor, Pennsylvanicum and others, which ought to be more common in our gardens. L. Japonicum and longiflorum, in which the genus attains its greatest magnificence, unfortunately require a finer climate than ours, and must therefore be grown in pots under glass.

Omitting *Crocus*, *Fritillaria*, and some other bulbous genera, which are sometimes treated as florists' flowers, we proceed to one of the prime ornaments of the autumnal flower garden, the *Dahlia*, or *Georgina*, as it is called by some writers.

The *Dahlia*, of which there are two species (D. variabilis and D. coccinea), is a native of Mexico, from which it was introduced in 1789, but afterwards lost by our cultivators. It was reintroduced in 1804; but it was not till ten years later that it was generally known in our gardens. The first plants were single, of a pale purple colour, and though interesting, as affording a new form of floral ornament, they by no means held forth a promise of the infinite diversity of tint and figure exhibited by their successors. At present the varieties are endless, each district

Flower Garden.

of the country possessing suites of its own, and cultivators occasionally raising at one sowing a dozen or two of sorts, which they think worthy of preservation. The results have been most propitious to the flower garden, from which, indeed, the Dahlia could nearly as ill be spared, as the potato from the kitchen garden.

The varieties of Dahlia may be classed under the following heads: 1. The *Common* or *Rose-shaped* form, under which the double sorts first appeared. This is by far the most numerous class, and perhaps the most beautiful. The dwarf sorts are in most repute. 2. The *Anemone-flowered*, having a radius of large petals, and a central disk of smaller ones, somewhat like the double anemone. 3. *Globe-flowered*, having small globular flowers, which are extremely double. They possess great intensity of colour, and, rising for the most part above the leaves, make generally as striking an appearance as those of a more massive efflorescence.

In a fine Dahlia the flowers should be fully double, always filling the centre; the florets should be entire or nearly so, regular in their disposition, each series overlapping the other backwards; they may be either plain or quilled, but never distorted: if, instead of being reflexed, the florets are recurved, the flower will be more symmetrical. The peduncles ought to be strong enough to keep the blossoms erect, and long enough to shew the flowers above the leaves. Bright and deep velvety colours are most admired.

New varieties are, of course, procured from seed. If sown in flower-pots, and aided by a little heat, the seedlings, speedily planted out, will flower the first season. Established varieties are propagated by dividing the large tuberous roots, but in doing so, care must be taken to have an eye to each portion of tuber, otherwise it will not grow. Sometimes shoots of rare varieties are grafted on the roots of others. A good method is to take cuttings close from the roots of the plants, as soon as they shoot up in the beginning of summer, and to strike them in small flower-pots. These will generally flower during the current season.

Dahlias succeed best in an open situation, and in rich loam; but there is scarcely any garden soil in which they will not thrive, with manure. They are, however, injured by being repeatedly planted on the same spot. They may stand singly like common border flowers; but have the most imposing appearance when seen in masses arranged according to their stature. Old roots often throw up a multitude of stems, which render thinning necessary. As the plants increase in height, they are furnished with strong stakes, to secure them from high winds. Dahlias generally flower till they are interrupted by frost in autumn. The roots are then taken up, dried, and stored in a cellar, or some other place, where they may be secured from frost and moisture.

The *Auricula* (Primula Auricula) is a native of the Alps and the Caucasus. It has long been an inmate of our gardens; and has generally been a favourite with those florists whose means and appliances are of a limited kind. Some of the most successful cultivators at present are among the operatives in the vicinity of Manchester and Paisley.

Besides the double varieties which have never been in much repute, Auriculas are classed under two divisions: the *Selfs* or plain-coloured, and the *variegated* or *painted* sorts. Professed florists confine their attention to the latter: it must, however, be confessed, that their criteria of fine flowers are often arbitrary, and that although many of their favourites are examples of undoubted beauty, the eye of the uninitiated would generally prefer the simpler hues of the self-coloured flowers.

The auricula, though now almost wholly an artificial plant, and strangely transformed from its original appearance, still loves a moist soil and shady situation. The florists' varieties are grown in rich composts, for the preparation of which numberless receipts have been given. We quote that of Mr Hogg, an experienced grower, as stated in his Supplement, p. 166. "One barrow of rich yellow loam, or fresh earth from some meadow or pasture land or common, with the turf well rotten; one barrow of leaf mould, one ditto of cow-dung, two years old at least; and one peck of river, not sea sand. For strong plants intended for exhibition, add to the same composition, as a stimulant, a barrowful of well decayed night soil, with the application of liquid manure before the top-dressing in February, and twice more, but not oftener, in March. A portion of light, sandy, peat-earth may be added, as a safe and useful ingredient, particularly for plants kept in low damp situations."

Auriculas may be propagated from seed. It is to be sown in January or February in boxes, which are kept under cover, and exposed only to the rays of the morning sun. When seed has been saved from the finer sorts, the operation is one of considerable nicety, as it not unfrequently happens that the best seedlings are at first exceedingly weak. They generally flower in the second or third year; and the florist is fortunate who obtains three or four good sorts out of a large sowing. The established varieties are increased by dividing the roots, an operation which is performed in July or in the beginning of August.

Fine auriculas are grown in pots about six inches in diameter. These are kept in frames, or stages constructed for the purpose. For winter use, perhaps there is nothing better than a common hot-bed frame, as this admits of an exact adjustment of air and temperature, things to which attention is absolutely necessary as the plants approach the flowering season. After the bloom is over, the pots may be placed on stages slightly elevated, and facing the north. Though not absolutely necessary, it is useful to have the power of sheltering them from long continued rains. It is usual every year to shift the plants, shortening the roots, and giving them a large portion of new soil, soon after the flowers have decayed. For more detailed information on this subject, we may refer to the well-known treatises of Maddock and Hogg.

The *Polyanthus* is supposed to be a seminal variety of Primula vulgaris; and is much cultivated by some florists. Like the auricula, it has sported into many hundred varieties. It is not necessary to give a detailed account of its culture, as it scarcely differs from that of the auricula. The polyanthus, however, is the hardier of the two, and seldom perishes from cold. It may be mentioned that there are several beautiful double varieties of the common primrose, which are deserving of a place in every garden.

The whole genus *Primula* merits the attention of the curious cultivator. P. helvetica and nivalis adorn the flower borders in spring with their abundant trusses of blossom. P. marginata, when planted in a shady situation, is equally lavish of its pale and delicately beautiful flowers. P. viscosa and integrifolia, with their intense colours, are the ornaments of the alpine frame; or, with P. longifolia, farinosa, and Scotica, may be plunged into the margin of the American border. A supply, however, should be kept in pots. Besides these we might name P. cortusoides, Pallasii, Palinuri, and others. The curious P. verticillata, and the splendid P. Sinensis, are inmates of the greenhouse. The florist of simple tastes will love them all.

The *Carnation* (Dianthus caryophyllus) has long been a favourite flower, not only for the beauty but for the delightful fragrance of its blossoms. It is a native of Germany, and it is occasionally found in an apparently wild state in England. The cultivation of it, however, is by no means easy, and calls forth all the resources of the florist. The varieties, which are very numerous, have been arranged under three heads: *Flakes*, having two colours, with their stripes running quite through and along the petals; *Bizarres*, irregularly spotted, and striped with not fewer than three colours; *Picotees*, spotted, with serrated or fringed petals. Mr Hogg, who has written a treatise expressly on this flower, has given a catalogue of nearly 350 sorts.

Carnations are propagated by layers or pipings: the former method is most practised, but with some sorts piping, it is said, should be preferred. Layering is performed when the plant is in full bloom. Proper shoots are selected; a few of the lower leaves are then removed; an incision is made a little below a suitable joint passing up through it, and the shoot is then pegged down and covered with some fresh soil, the tip being left above ground. Layers are generally found to be rooted in about a month after the operation has been performed. Pipings are little cuttings, separated at a joint, and planted thickly under bell-glasses on a slight hot-bed. They require great attention, and are precarious in their success, but form excellent plants.

Numerous directions have been given respecting composts for carnations. We abridge those of Hogg, who is principal authority in this matter. Take three barrows of loam, one and a half of garden mould, ten of horse-dung, and one of coarse sand; let these be mixed, and thrown into a heap, and turned over two or three times in the winter, particularly in frosty weather. Towards the end of November a barrow-load of lime is added while hot, to aid in the decomposition of the soil, and destroy worms. For the varieties which are liable to sport, he recommends a poorer compost.

The more robust carnations are planted out in beds or singly in the flower garden; but the finer and tenderer sorts are grown in pots of about a foot in diameter. The time of potting is about the end of March. When the flower-stems shew themselves, they are furnished with rods, to which they are tied as they lengthen, to prevent their being broken by the wind or other accident. When the plants begin to expand their blossoms, they are removed to a stage calculated to exhibit their beauties. Some florists attach ligatures of matting to the flower-buds, in order to prevent irregular bursting, and even arrange the petals, by removing distortions with scissars.

New varieties are raised from seed. The seed of the hardier double or semidouble sorts often affords a very beautiful bed of flowers, and should not be neglected by those who have the command of extensive flower gardens.

The *Pink* is considered by botanists as merely a variety of the preceding. It is, however, very distinct in its character, and constant in its habits. It is one of the mechanics' flowers, and is cultivated most extensively in the neighbourhood of some of the manufacturing towns. Its simple elegance does credit to the taste of those who select it for their favourite; and it deserves a place in the garden of the highest as well as of the lowest in the land. Pinks are numerous, the growers at Paisley enumerating about three hundred varieties. Those are preferred which have the limb of the petals nearly entire, and are well marked in the centre with bright crimson or dark purple.

Pinks are mostly propagated by pipings in slight hot-beds or under-hand glasses; and when proper attention is given to the due admission of air, they generally succeed. Occasionally rare sorts, which are scantily furnished with grass, are propagated by layers. This flower does not require such elaborate composts as some others, but it likes fresh light soils, well manured with decayed cow dung. Not more than two years of blooms should be taken from the same bed, and it is the practice of most florists to have a new bed every year. The flower stalks are supported by small sticks. As in the carnation, ligatures of matting, or collars of card, are sometimes applied to the calyces of the flowers: but this practice, however it may be followed by those who judge according to the technical "criteria of a fine flower," will scarcely be adopted by any who have an eye for natural beauty.

The genus *Lobelia* may now be regarded as affording a group of florists' flowers. L. Cardinalis, the cardinal flower, has long been a valued but somewhat rare plant. It is propagated by seed or by off-sets. L. fulgens is a more shewy species, which, when potted and treated as a tender annual, forms a magnificent plant. It also succeeds perfectly well in the open borders. Being a semi-aquatic, it may be preserved during winter in springs or cisterns. We have seen quantities kept most successfully at the mouth of an Artesian spring at Hopetoun House. L. splendens is also worthy of notice. Besides the quaint L. tupa, there are many other species, particularly the blue and yellow procumbent sorts, which merit a place in every collection of fine flowers.

It would lead us too much into detail to speak minutely of Calceolaria, Phlox, Chelone, Pentstemon, Œnothera, and other genera, which approach the character of florists' flowers. To have them in perfection, they should be kept in beds by themselves: and we are persuaded that, were a moiety of the care bestowed upon some of the preceding flowers, which are conventionally supposed to belong peculiarly to the florist, expended on them, they would amply repay the labour of the cultivator.

The *Chinese Chrysanthemum* (Chrysanthemum sinense), from the peculiar culture which it now undergoes, may be considered to belong to this department of flowers. It is a native of China, and though introduced many years ago, its ornamental capabilities have only recently been brought into notice. Flowering in November and December, it fills up, with its many coloured blossoms, the blank of a most dreary season, and affords the means of decorating greenhouses, conservatories, and dwelling-houses, when almost all other means of embellishment fail. Forty varieties have been enumerated by Mr Sabine in the London Horticultural Memoirs, but it is believed that there are many others not yet introduced from China. The Chrysanthemum is hardy enough to live in the open air, but it requires the shelter of a wall, and from the lateness of its flowering, it is only the early varieties that, even in fine seasons, are permitted to unfold their blossoms. It is seen in its beauty only when grown in pots. Yearly plants are preferred. In the beginning of April, cuttings of the last year's shoots, about three inches long, are put singly into small pots, filled with soil composed of one half bog earth or leaf mould, and one half pure sand. Their growth is expedited at first by gentle heat. In about a month they are rooted and are put into a cold frame, in which they are kept till the beginning of June, when they are put into larger pots, and set out in some airy situation. About this time the tops of the plants are pinched off to make them bushy, but no more side shoots are allowed to remain for flowering than the plants are likely to be able to support. In August they are again shifted into larger pots, filled with strong rich soil. During the whole season, the pots are frequently moved to prevent the roots from striking through, and they are never plunged. Mr Monro of the Lond. Hortic. Garden, whose method of culture we have been describing, recommends liquid manure to be applied from time to time in summer and autumn. Other cultivators, in order to have a greater succession of flowers, and a variety in the stature of the plants, strike cuttings at two seasons, in March and in May, and propagate by layers in August. In the beginning of winter the plants are put into a cold frame or vinery, and they are brought into a milder temperature as they are wanted. To produce large shewy plants, a few of the chrysanthemums of the former year may be selected, and, being freed from suckers, and having the mould shaken from their roots, may be repotted and shifted repeatedly during the summer and autumn.

BOTANICAL STRUCTURES.

Glazed houses, for the reception and culture of exotic plants, though sometimes placed in connection with similar structures in the forcing department, are now almost universally regarded as appendages of the flower garden. In the hands of architects they have assumed a great variety of forms. We shall confine ourselves to the exhibition of the principle of the most important of these, and shall limit our remarks to the Greenhouse, the Conservatory, and the Stove.

The *Greenhouse* is intended to afford a winter and partly a summer shelter to the less tender classes of exotic plants grown in pots. Fig. 5, Plate CCXCIII., exhibits the old *lean-to* greenhouse. The general form of the house is that of a vinery with pretty lofty front glass. The main part of the area is occupied by a stage rising in steps to receive the potted plants. At some height above the front flue is placed a narrow horizontal bench of trellis work to receive small plants which require to be near the light. The interior air is warmed by one or two flues, or other heating apparatus, according to its volume; but a temperature of 45° Fahr. during winter is sufficient. Sometimes greenhouses are constructed with span-roofs and a double stage. They may indeed assume any form which taste can suggest, provided there be a sufficiency of light, and the plants be not too far from the glass. The *heath-house* does not essentially differ from the greenhouse, but for it a span roof is certainly preferable.

In the *Conservatory* the chief plants grow in beds of earth sunk in the floor. Fig. 3, Plate CCXCIII. shews the principle of this species of house. The beds marked *b b* are filled with a light soil calculated for the plants which are to inhabit them. Fig. 4. represents the front elevation of the roof. Numerous varieties of this structure also have appeared, and some most sumptuous examples have been erected in the gardens of the nobility. With similar restrictions as in the greenhouse, the conservatory may be said to be capable of assuming any form.

The *Plant Stove* may be either a *dry stove* or a *bark stove*, or both combined, and is applied to the cultivation of tropical plants which require an elevated temperature. The dry stove may be considered as a greenhouse with a larger than usual apparatus for the production of heat. The bark stove is furnished somewhat in the manner of a pine stove, with a receptacle to contain a bed of fermenting tanners' bark into which the pots are plunged. In this country, stoves are regarded as belonging rather to the botanic than to the flower garden; they are extremely useful, however, in the latter, for, besides presenting the florist with many unusual forms of vegetation, they afford in summer a variety of beautiful plants, which, when in flower, may be introduced into the greenhouse.

Sometimes the various botanical structures are combined into one imposing assemblage, as that exhibited in Plate CCXCIII. Fig. 1, the ground-plan of which is given in Fig. 2 of the same plate; *a* being a palm-house; *b* for New Holland plants; *c* large greenhouse; and the intermediate spaces being occupied by dry stove, heath-house, and greenhouses. This mode is, of course, suited only for places of the first order, where splendour is the object, where every thing is on a great scale, and expense little regarded. In a vast proportion of cases economy must be studied; and in villa gardens the ornamental plant-house is very often attached to the library or the drawing-room. A good plan for such a glazed house may be found in the Gardener's Magazine, vol. vi. p. 664.

Greenhouse Plants.—This beautiful class of plants have become so numerous, that, in a sketch like the present, it is impossible to give the names of even a limited selection. We may once more refer to Mr Loudon's tables in his *Encyclopedia of Horticulture*, or to his still more copious lists in the *Hortus Britannicus*, in both of which works much valuable information may be obtained. The recent increase of species makes the work of selection at once more necessary and more difficult; a work which it must be confessed is often negligently performed. Many of the finer sorts of woody plants are propagated with difficulty, and consequently, being high priced in the nurseries, are possessed in requisite abundance only where there is considerable liberality on the part of the proprietor. On the other hand, the species which strike easily are circulated by gardeners themselves, many of whom, by their own interest and resources, more than half fill their greenhouses without calling for the aid of their employers. To this cause may be ascribed the perpetuation of many mean looking plants, which, if hardy, would scarcely be tolerated in well-kept shrubberies, and certainly ought not to encumber the greenhouse.

Light mould produced by the rotting of turf from pastures, and reduced with sand if necessary, or enriched with leaf-mould, is well adapted for most greenhouse plants. Some require a mixture of peat earth: others thrive only in pure sandy peat. If more specific directions be wished, we would recommend the reader to have recourse to *Cusking's Exotic Gardener*, or to the more recent work by Sweet, entitled *The Botanical Cultivator*. The common means of propagation is by cuttings, inserted in earth or sand, and covered, if necessary, with bell-glasses. A few sorts are increased by grafting or layers. Nearly all may be raised from seed, large quantities of which are annually imported from abroad; and, it may be added, many greenhouse plants ripen their seed in this country.

Many of these plants require shifting and fresh earth twice a year; all of them should be repotted once a year at least. It is the common practice to examine their roots in spring or the early part of summer, and, removing the matted fibres, to put them into larger pots if necessary. As room is extremely valuable in limited greenhouses, it is desirable that the plants should be kept of a moderate size; and they are, therefore, rather to be under-potted than otherwise. Many of the free-growing plants require to be shifted again in August; at which period of the year, it is considered preferable to repot those which require to be disturbed only once a year. During the summer months, a great proportion of the inmates of the greenhouse are placed in the open air, on a spot paved or laid with ashes, to prevent the entrance of earth-worms into the pots, and not too much exposed to winds. Meanwhile, their place in the greenhouse is occupied by balsams and other tender annuals of a showy character. On the approach of winter the plants are again placed under cover. All that is necessary in the management of the greenhouse in winter, is to keep up a steady but very moderate temperature, to preclude the access of damp by regular airing in mild dry weather, and to attend to moderate watering where it may be needed.

Of late years, particular genera of plants have come greatly into vogue, and it would be an omission not to notice some of them. Among the foremost may be mentioned *Pelargonium*, with its affinities. This beautiful tribe has varied nearly as rapidly as the Dahlia; to the discomposure of some botanists, whose scientific logic has been brought into jeopardy. Pelargoniums are of easy culture, propagating readily by cuttings, and requiring only to be shifted from time to time. Equal to these in point of beauty of colour, and certainly superior in elegance of form, is the family of Cape heaths, the *Ericæ* of botanists. Of this genus there is said to be 600 species, considerably more than the half of which exist in our collections. Many heaths may be raised from seed, which occasionally ripens in this country: the most common mode of propagation, however, is by cuttings, and this in some species is attended with difficulty. Heaths require a peaty soil, and attention in watering. For further information, we may refer to the excellent little treatise of Mr M'Nab of the Botanic Garden, Edinburgh, whose success in this department is quite unrivalled, and in whose hands heaths attain a splendour which, we believe, they never reach in the environs of Table Mountain itself. The superb genus *Camellia* is the only other that particularly claims our attention. To the elegance of the finest evergreen it unites the beauty of the fairest rose. The Camellia, though a native of Japan, is not particularly tender, but from some peculiarities in its constitution, its culture requires a considerable degree of attention and care. Cuttings of the single red variety strike freely, and upon these as stocks, the finer sorts are grafted by inarching or side-grafting. The soil generally employed is a mixture of peat and light loam. Care must be taken not to allow the roots to become matted in the pots. The young plants should be shifted at least once a year; when old, and in large tubs, once in two years will be sufficient. It is found beneficial to apply a certain degree of heat while the plants are growing, and till they form flower-buds for the following season. To have Camellias in perfection, a house with a span roof should be appropriated for their reception. There are some splendid collections of this noble plant in the nursery-gardens in the neighbourhood of London, particularly at Hackney, Vauxhall, and Clapton.

Conservatory Plants.—These are composed of a selection from the numerous inmates of the greenhouse. They should be naturally of an elegant form, capable in general of sustaining themselves, and somewhat hardy in their constitution. Many of the Australian plants, particularly the Acacias and Banksias, are well adapted for this purpose. The ascending Proteas of the Cape, Clethra arborea of Madeira, and many others of a similar habit, may likewise take their place in this department. To these may be added a few of the hardier Heaths and Camellias, together with a Myrtle or two, double flowering Pomegranate, Camphor-laurel, Tea-tree, and some of the varieties of the magnificent and consecrated Rhododendron arboreum. Any wall in the interior of the house may be furnished with a trellis, and covered with such climbing plants as Lonicera Japonica, Cobbea scandens, Maurandia semperflorens and Barclayana, and the trailing Pelargoniums. In the management of the conservatory, abundant air should be admitted, and care should be taken not to *draw* the plants; that is, not to cause them to become too tall and spindle-formed by over-crowding. They should be so pruned as to keep them comparatively short and bushy; but after all pains have been taken, the sorrowful time at length arrives, when they either disfigure themselves by pressing against the glass, or must submit to the no less distorting process of a violent amputation. To meet such exigencies, it is recommended that, wherever there is also a greenhouse, a few plants should be kept in training for the conservatory, and substituted in the room of any that become unmanageable. After all, the fourth, fifth, and sixth, summers of the conservatory will always be the finest: and when a longer series of years have gone by, and the plants have outgrown the space allotted to them, perhaps the best thing that can be done is to change the whole interior of the house, plants, earth and all. If this operation be anticipated, and for a year or two prepared for, sufficiently large plants may be had in readiness, and the appearance of a well-furnished house be attained in one or two seasons. It is scarcely needful to add, that the neatness which is so desirable everywhere in the flower-garden is absolutely indispensable in the conservatory.

Stove Plants.—There are many beautiful plants, natives of tropical regions, which are cultivated in our stoves, but which, from the elevated temperature they require, can be only occasionally visited with pleasure. This may account for the fact that stoves are seldom found but in first-rate gardens, even where the price of fuel is inconsiderable. It is unnecessary to be minute respecting *dry stove* plants: their culture is precisely that of greenhouse plants, differing only in the degree of heat. Many dry stove plants are succulent, such as Cactus, Aloe and Mesembryanthemum, and of course require an arid soil, composed of a little light loam mixed with lime-rubbish or shivers. One of the most successful growers of the cacti was the late Mr Walter Henderson at Woodhall. The compost which he employed consisted of 1 part rotted dung, 1 rotted leaves, 1 heath mould, 1½ loam, and 1 coarse sand, all well mixed together; and the pot was nearly one-third filled with shreds, so as to form an effectual drain. Some of the species, such as Cactus speciosus and Cereus flagelliformis, are improved, and made to flower more freely, by being kept growing vigorously in the greenhouse during summer. The *bark stove* plants thrive best in the tepid vapour peculiar to the equatorial climes. In order to furnish bottom heat, a bark pit is prepared, into which the pots or tubs are sunk; and the atmosphere is heated by flues, by steam, or, what is better, by a circulation of hot-water. Along the front glass, and on the back wall, are shelves on which pots may be arranged, according to the necessities of light and shade. On the front shelves are occasionally placed shallow troughs, filled with old tan, leaves, or decayed wood, for the reception of the air-plants and other epiphytes. Small cisterns too are introduced to contain tender aquatics. Along the rafters some of the more elegant species of Passiflora, such as P. quadrangularis, may be trained; and through the branches of some of the woody plants, Cuscuta, Tropæolum, and other tender climbers, may be allowed to twine themselves. In the pit may be plunged some of the Palms, those princes of plants. In short, there is no end of those numerous tribes, "the potent sons of moisture and of heat," with which the teeming regions of the equator are filled; and no suite of stoves in this country, however extensive, can come up to the wishes of the botanist. The management of this department of floriculture is laborious and trying to the constitution. A strong heat, both in the bark bed and in the atmosphere, must be maintained; the air must be kept charged with vapour, and the plants require frequent shifting and repotting. For more detailed information as to the management of particular stove plants, we may again refer to Cushing, who, in his *Exotic Gardener*, has treated this subject with a skill and fulness that have not been surpassed, perhaps not equalled, by any of his successors.

CALENDAR.

January.

Kitchen Garden.—Sow early frame and Charlton pease in the beginning of the month, and dwarf marrowfats about the end of the month; early mazagan and longpod beans during the first and last weeks; onions, on very light soils; as also parsley, if not done in August, on a warm border; short-topped radish in two or three sowings, at a week's interval, in the same situation. In the last fortnight sow hardy green and brown Dutch lettuce.

Plant fruit trees, in general, in open weather, mulching the trees to protect them from the drought which may occur in spring. Plant shallot.

Prune all sorts of fruit trees in mild weather or in moderate frosts, nailing only in fine weather: wash those trees infested with insects, with soap-suds, flowers of sulphur, and tobacco liquor.[1]

Forcing Department.—Prepare for making up hot-beds for early cucumbers and melons, at least where a pit heated with hot water is not in use. Sow salads, carrots, and kidney-beans on slight hot-beds. Sow pease in cold frames for transplanting. Force asparagus, sea-kale, and rhubarb, in hot-beds, in pits, in the mushroom-house, or in the open garden by covers surrounded with litter. Give air in fine weather, and water sparingly, to the pinery and cucumber-pit; and to other forcing houses, according to the progress of the trees. Attend to the forced kidney-beans and strawberries. Give abundance of air to the greenhouse, conservatory, and alpine frame, but little water. Begin to force roses, kalmias, rhododendrons, &c., and hardy flowers and bulbs.

Flower Garden.—Plant dried tubers and bulbs of border flowers, if not done in autumn; but roots of the finer florists' flowers ought to be deferred till next month.

Transplant herbaceous plants and evergreen shrubs in light soils, if not done in autumn; also deciduous trees, shrubs, and hedges. Lay edgings in fine weather.

Sow mignonette, stocks, &c., in pots; sow pease, and a few hardy annuals, on a warm border. Give stage auriculas and carnations abundance of air; but keep them rather dry, to prevent damping off.

FEBRUARY.

Kitchen Garden.—Sow beans and pease in the beginning and end of the month; a few early cabbages, to replace the last sowing in August; red cabbages and savoys in the last week. Sow also early horn carrot; Dutch turnip; onions for a full crop in light soils, with a few leeks. Sow chervil and fennel, and lettuce for succession, with radishes and round-leaved spinach, twice in the course of the month; small salads every fortnight.

Plant Jerusalem artichokes, garlic, horse-radish, and early potatoes. All sorts of fruit trees may still be planted. Strawberries may be planted about the end of the month. Transplant for seed, if not done before, all the brassica tribe, including cabbage, cauliflower, turnip, &c.; also carrots, onions, beet, celery, endive, leeks, and parsneps. Transplant to the bottom of a south wall a few of the pease sown in November for the first crop.

Prune apricots, peaches, nectarines, and plums, before the buds be much swelled; also apples, pears, cherries, gooseberries, currants, and raspberries, before the end of the month. Finish the dressing of vines, keep the fruit-room free from spoiled fruit, and shut it close.

Forcing Department.—Plant out melons and cucumbers on hot-beds and in pits, sowing more for succession. Sow carrots, turnips, and early celery; cauliflower, to be afterwards planted out. Plant early potatoes on slight hot-beds. Continue the forcing of asparagus, rhubarb, and sea-kale. Pine-apple plants require little air or water at this season, except young plants in dung-frames, which ought to be kept free from damp. Shift fruiting plants by the middle of the month, if not done in August. Continue the forcing of all sorts of fruits. Those who have not commenced sooner will find this one of the best seasons to begin. Be careful to protect the stems of vines that are outside of the forcing houses.

Let the greenhouse and conservatory have plenty of air in mild weather. Put in an extra quantity, if not done in autumn, of cuttings of Pelargoniums, Fuschsia, Salpiglossis, Calceolarias, Heliotropium, and Salvia splendens, for the flower garden. Sow stocks, a few tender annuals, and dahlia seed, on a slight hot-bed, or in pots.

Flower Garden.—In good weather plant dried roots, including most of the finer florists' flowers; continue the transplanting of hardy biennial flowers, and herbaceous plants, shrubs, and deciduous trees.

Sow in the last week mignonette, and hardy annuals, in a warm border, for subsequent transplanting.

MARCH.

Kitchen Garden.—Sow main crops of pease, beans, cabbages, onions, leeks, carrots, parsneps, Brussels sprouts, borecoles, lettuces, and spinach. In the beginning, and also in the end of the month, sow turnips and savoys. In the last fortnight sow asparagus, cauliflower, sea-kale, cardoons, celery, and most of the culinary aromatics, as dill, fennel, parsley. Small salads should be sown every ten days.

Plant early potatoes in the first week, and a main crop during the last fortnight. Jerusalem artichokes, sea-kale, asparagus, and pease raised in frames, may now be planted. Full crops of cabbages should now be planted out, and cauliflowers under hand-glasses. Propagate by slips the various pot-herbs, as mint, sage, savory, tansy, &c.

Fruit Garden.—Finish the planting and pruning of fruit trees before the middle of the month. Protect those coming into blossom. Begin grafting in the third week; dig and dress between the rows of gooseberries, currants, and other fruit trees, if not already done. Kill wasps when they first appear, for the death of every individual now is equal to the destruction of a colony in autumn.

Forcing Garden.—Proceed with the forcing of melons and cucumbers, giving air, and applying linings to maintain the proper temperatures. Examine pine-suckers and crowns, potting those that are kept in tan during the winter; repotting those that require large pots, and dressing the roots of such as are sickly; about the middle of the month, shift to the succession pit, and give a top-dressing to the fruiting plants; turn the tan, and add new bark to the pits, to keep up bottom heat. In the vinery and peach-house, attend to the keeping down of insects by watering; and promote the growth of the young shoots, by steaming in the evenings. Sow the seeds of capsicum and tomato.

Greenhouse.—More water may be given than formerly. Sow seeds of greenhouse and hot-house plants; also the different sorts of tender annuals; pot off those sown last month; shift greenhouse and stove plants; plant tuberoses in pots for forcing. Begin to propagate greenhouse plants by cuttings.

Flower Garden and Shrubbery.—In the last week, sow hardy annuals in the borders, with biennials that flower the first season; as also perennials. Plant anemone and ranunculus roots. Transplant from the nursery to their final sites annuals sown in autumn, with biennials and herbaceous plants Propagate perennials from root-slips and offsets. Protect tulips, hyacinths, and choice flowers, from severe weather. In the last week put into heat the finer sorts of dahlias, so as to spring them, and prepare them for propagation by cuttings and by division of the roots. In the first week finish the planting of hardy deciduous trees and shrubs; evergreens by the middle; but some of the hardier sorts may still be planted towards the end of the month. Likewise finish the pruning of all deciduous trees and hedges as soon as possible. Attend to the dressing of shrubberies, laying of turf-edgings, and to the state of gravel walks.

---

[1] We have not deemed it necessary to treat separately, or at length, of the means of destroying insects; many of the nostrums recommended proving very inefficient. The wash here mentioned is perhaps the best and simplest for the stems and branches o wall fruit-trees. Some prefer making it of the consistence of paint, and laying it on with a brush. One advice we would tender to all gardeners,—not to be anxious to kill the smaller kinds of the feathered songsters, the soft-billed warblers of the garden, which are often suspected of attacking blossom or fruit, when they are only picking off caterpillars or aphides, their favourite food. In hot-houses, the keeping of the walls and frame-work clean, by frequent white-washing and painting, is very important; and much benefit results from occasionally filling them with the smoke of tobacco-paper, and then thoroughly syringing.

APRIL.

Kitchen Garden.—Sow asparagus, sea-kale, beet, salsify, scorzonera, skirret, carrots, and onions on heavy soils; also pease, beans, turnips, spinach, celery, cabbages, savoys, and German greens, for succession. Sow broccoli and kidney beans both in the second and in the last week; and small salads should be sown twice or thrice during the month; also all sweet herbs, if not done last month.

Plant cauliflower, cabbages, sea-kale, lettuce; and finish the planting of the main crops of potatoes. Propagate all sorts of pot-herbs, and attend to the hoeing and thinning of spinach, onions, turnips, &c. Earth up cabbages, cauliflower, pease, beans, and early potatoes. Stake up pease; blanch sea-kale and rhubarb in the open air, by covering with straw or leaves.

Fruit Trees.—No pruning ought to be left undone till this period; stone fruits, in particular, are much injured by spring pruning. If vines have been neglected, rubbing off the buds that are not wanted is safer than pruning. Protect the finer sorts of fruit-trees on the walls.

Forcing.—Continue the preparation of succession beds and pits for cucumbers and melons. Sow gourds and basil. Pot love-apples and capsicums. Attend to the routine culture of the pinery, giving water and air when necessary. Keep up the bottom heat with linings and additions of new tan. In the forcing houses, from the variable state of the weather considerable vigilance is required in giving air. Keep down red spider (acarus) in the more advanced houses by frequent waterings. Continue the usual operations of disbudding and thinning of fruit, and take care to keep up the proper temperatures.

Greenhouse.—Still sow all sorts of tender annuals. Proceed with all necessary shiftings. Propagate rare and fine plants by cuttings or grafting. Pot off tender annuals, and cuttings of half-hardy greenhouse, plants put in in February for the use of the flower garden.

Flower Garden and Shrubbery.—Sow main or succession crops of annuals of all sorts; half hardy annuals in warm borders, or on slight hot-beds. Biennials and perennials should be sown before the middle of the month. Plant Tigridia pavonia and fine stocks. Finish the transplanting of herbaceous plants by the end of the first week. Protect stage auriculas and hyacinths from extremes of every description of weather; and tulips from hoarfrosts and heavy rains. Plant out tender deciduous trees and shrubs raised in pots. Remove part of the coverings of all tender shrubs and plants in the first week, and the remainder at the end of the month. Form and repair lawns and grass walks, by laying turf and sowing perennial grass-seeds.

MAY.

Kitchen Garden.—Sow small salads every week; radishes and lettuces thrice; spinach once a fortnight; carrots and onions for late drawing; kidney-beans in the first week and last fortnight. Pease and beans, cauliflowers, cabbages, Brussels sprouts, bore-cale, broccoli, savoys, and German greens, for late crops. Sow pumpkins and cucumbers on a warm border in the last week. Continue the various operations of hoeing and earthing up the different crops.

Fruit Trees.—Disbud peaches, nectarines, and other early trees against the walls; also attend to the thinning of fruit. Give occasional washings with the engine to keep down insects. Pick caterpillars from gooseberries and wall trees on their first appearance. Mulch, if not done before, all newly planted fruit trees, watering abundantly in dry weather. Remove from raspberries and strawberries all suckers and runners that are not wanted.

Forcing.—Plant melons, and cucumbers, and some basil, on the hot-beds prepared for vegetables in February, and now free. Plant out pumpkins on dung-ridges, under hand-glasses. Sow late crops of cucumbers and melons; attend to the various particulars in their culture, heat, air, water, shade, and insects. Go on with the usual culture of the pinery; give abundance of heat and water, keeping down all manner of insects.

Greenhouse. Turn out all hardy plants about the middle, and the more tender at the latter end of the month. Sow tender annuals for succession; potting and shifting all those sown at an earlier period. Pot off, likewise, all rooted cuttings. Put in cuttings of the different desirable species which are now fit for that purpose. Sow a few hardy annuals and ten-week stock, &c. for late crops.

Flower Garden.—Sow annuals for succession; biennials in the last week, in the nursery compartment, for next year. Propagate by cuttings, dahlias, pansies, double wallflowers, rockets, scarlet lychnis, and lobelias, by dividing the roots. Plant out, during the first week, dahlias, hardy pelargoniums, stocks, and calceolarias, protecting the dahlias from slight frosts. By the middle and end of the month, masses of the following plants may be formed with safety: pelargonium, heliotropium, fuschsia, salpiglossis, nierembergia, salvia, verbena, bouvardia, erica, and lobelia. Protect tulips, ranunculuses, and anemones, from the mid-day sun, from rains, and winds. Remove the coverings from all tender plants in the open air.

Shrubbery.—Planting out of tender evergreens from pots may be continued, but any other kind of transplanting will be carried on at considerable risk, except in very moist and cloudy weather. Proceed with the laying down of lawns and gravel-walks.

JUNE.

Kitchen Garden.—Sow pease and beans for late crops. The kinds used for early crops are likewise best for this purpose. Sow salading every ten days; also carrots and onions for drawing young. In the beginning of the month sow endive for an early crop. In the first week sow turnips for succession; and in the third week for a full autumn crop. Scarlet and white runners for a late crop; cabbages for coleworts.

Plant full crops of broccoli, Brussels sprouts, savoys, German greens, and leeks; ridge out early celery, successional crops of cabbage and cauliflower. In the first fortnight of the month, plant cucumbers for pickling, in a warm border, placing hand-glasses over them. Pull and store winter onions.

Fruit-Trees.—Train and prune the summer shoots of all descriptions of wall and trellis trees. Standards do not require this, except those are trained *en pyramide* or *en quénouille.* Mulch and water fruit-trees and strawberries in dry weather, desisting from watering as soon as the fruit begins to ripen. Net over cherry-trees, to protect the fruit from birds. Destroy insects by frequent washings, and directing tobacco-smoke against them, or by strewing snuff (or the fine powder of tobacco) over them. In the first week, plant out love-apples in vacant spaces along the bottom of a south wall.

Forcing and Greenhouse Department. Hot-beds and Pits.—Proceed with planting melons and cucumbers raised from seeds and cuttings, for late crops. Keep up, by

Calendar.

linings, the necessary temperatures for ripening of the fruits. Continue the cultivation of the pinery stated for last month; but, if you wish very large-sized fruit, and do not care about preserving suckers, remove the whole suckers from the stem and roots, and apply heat and water in abundance. Shift suckers and succession plants in the beginning and middle of the month, as the state of the plants may require.

Forcing-houses may have the same treatment as stated last month. Little water and a good deal of air must be given to those houses where the fruit is beginning to ripen. Those in which the fruit is past, ought to be constantly under a system of thorough ventilation.

The *Greenhouse* will now be occupied with tender greenhouse plants and annuals, and the more hardy plants from the stove, for here they will remain longer in flower. Shift, re-pot, and propagate all plants, fine perennials, biennials, or annuals, and cuttings of all sorts that are desirable. Sow fragrant or showy annuals, to flower in pots during winter.

Flower Garden.—Take up bulbs and tuberous roots, and dry them in the shade before you remove them to the store-room. Fill up with annuals and greenhouse plants those beds from which the bulbs and roots have been raised. After this season, keep always a reserve of annuals in pots, or planted on beds of thin layers of well-rotted hot-bed dung, from which they are easily removed with balls, to fill up any blanks which may occur in the border or parterre. Sow perennials, if neglected last month, to be planted out in the spring. Lay and pipe carnations and pinks in the end of the month.

July.

Kitchen Garden.—In the first week, sow pease for the last crop of the season. In the last week, sow yellow turnip for a full winter crop, and spinach for an early winter crop. Endive, for autumn and winter crops, in the beginning and end of the month; also successional crops of lettuce and small salads.

Plant full crops of celery, celeriac, endive, about the middle and end of the month; late crops of broccoli, cauliflower, and coleworts, in the last week. Gather and dry medical and pot herbs; also propagate such by slips and cuttings.

Fruit-trees.—Continue the summer pruning and training of all wall and espalier-rail trees, with the destruction of insects. Plant strawberries in pots, for forcing next winter. Propagate different sorts of fine fruit-trees, by budding on other trees, or on prepared stocks.

Forcing.—Attend to the pruning of melons and cucumbers, giving air and water, renewing linings, &c. Go on with the usual cultivation of the pinery, but withhold water from the plants when the fruit begins to ripen. Have the old plants with suckers on them put into a brisk bottom-heat, giving proper supplies of water; this will increase their size very much, and materially shorten the period of their coming into fruit. The forcing-houses ought to have the same treatment as stated for last month.

In the *Greenhouse*, little alteration will take place in the culture and management from that given for last month; necessary attention being paid to potting, shifting, and putting in cuttings, and giving abundance of water to the potted plants, both in the house and out of doors.

Flower Garden and Shrubbery.—Take up the remainder of tuberous roots, such as anemone, ranunculus, &c., finishing by the end of the first week; fill up their places, and any vacancies that may have occurred, with annuals from the reserve ground. Propagate herbaceous and other plants that have gone out of flower, by means of cuttings and slips; also roses and American shrubs, by laying, budding, or cuttings. Go on with the laying and piping of carnations and pinks; attend to the staking and tying up of dahlias and strong herbaceous plants.

August.

In the *Kitchen Garden*, sow winter and spring spinach in the beginning and about the end of the month; parsley and winter onions, for a full crop, in the first week; cabbages, cauliflower, savoys, and German greens, about the middle of the month, for planting out in spring; lettuce in the first and last week; small salads occasionally; black, Spanish, red and white queen radish, for winter crops.

Plant and earth up celery and endive. A few coleworts may still be planted.

In the *Fruit Garden*, proceed in the training and regulation of summer shoots of all fruit trees as directed for the three last months. Mat up, in dry weather, gooseberry and currant bushes, to preserve the fruit till late in the autumn. Every exertion must now be used by the gardener to preserve the ripening fruits on the walls from insects, and to destroy wasp nests.

Forcing.—The same routine of cultivation in hot-beds and pits may be proceeded in as stated for last month. Sow, and propagate by cuttings, in the beginning of the month, cucumbers, to be afterwards grown in hot water pits, or in boxes in the front of the pine-stove, for a winter crop. In the pinery most of the fruit will be cut by the middle of the month, when a general shifting of succession plants will take place; as also a potting of suckers; but these will be strengthened by being allowed to remain on the old plants until the end of this month. In the forcing-houses where the crops are past, part of the sashes may be removed, so as to permit thorough ventilation.

Greenhouse.—Attend to the propagation of all sorts of greenhouse plants by cuttings, and to the replacing in the greenhouse and stoves the more tender species, by the end of the month in ordinary seasons, but in wet weather in the second week. Sow half-hardy annuals, as Clarkia, Schizanthus, Coreopsis, &c., to flower during winter.

Flower Garden and Shrubbery.—Sow in the second and the last week, on a warm border of a light sandy soil, with an east aspect, for planting in spring, Clarkia pulchella and elegans, Coreopsis tinctorea, Oenothera Lindleyana, and rosea-alba, Collinsia grandiflora, Schizanthus pinnatus, &c. Auricula and Primula seeds in pots and boxes. Propagate all sorts of herbaceous plants by rooted slips; lay chrysanthemums; take off layers of carnations, pinks, and pansies. Transplant evergreens in moist weather, about the end of the month; and propagate them by layers and cuttings.

September.

Garden.—Sow a few small salads for late crops; lettuce and spinach, if not done last month, for spring crops. Plant endive and lettuce. If broccoli be too strong or tall to withstand the winter, lift them and lay them nearly up to the neck in the earth. Lift onions, and lay them out to win on a dry border or gravel walk. Lift potatoes and store them.

Fruit Trees, &c.—Finish the summer pruning and training. Assist the maturing of the fruit, and, what is equally important, the ripening of the young wood for next year, of peaches and nectarines on hot walls, with fires during the day. Gather and lay up in the fruit-room with care the autumnal sorts of apples and pears. Plant strawberries for a main crop.

Forcing.—Take care that late crops of melons and cucumbers be not injured by damping, from getting too much water and too little air. In the pinery the usual routine of cultivation may be carried on; in the first week take off and pot all strong suckers, if not done in the middle of last month; the remainder may be taken off at the end of the month, and planted in old tan in a frame or pit prepared for that purpose. In this way they will be found to keep much better over the winter, and to be better supplied with roots, than if they had been potted, which ought never to be done after this season. Expel damp, and assist the ripening of late crops of grapes and peaches, with fires during the day. Prune early vines and peaches.

Flower Garden, &c.—Sow in the beginning of this month all half-hardy annuals stated for last month, if not done at that time. Sow also the different species of primula; and the seeds of all such plants as, if sown in spring, seldom come up the same season, but if sown in September and October vegetate readily the succeeding spring. Continue the propagation of herbaceous plants, taking off the layers of carnations, pinks, pansies, and chrysanthemums, by the end of the month. Plant evergreens; lay and put in cuttings of most of the hard-wooded sorts of shrubby plants.

October.

Kitchen Garden.—Sow small salads and radishes in the first week; Mazagan beans and early frame pease in the last week. If the winter prove mild they will be somewhat earlier than those sown next month or in January.

Plant cabbages in beds or close rows till wanted in spring. Cauliflowers in the last week, to receive the protection of frames, or, at any rate, at the bottom of a high wall or hedge in a sheltered situation.

Store potatoes, beet, salsify, scorzonera, skirret, carrots, parsneps, by the end of the month.

Fruit Garden.—Such fruit trees as have dropped their leaves, may be transplanted. Protect fig-trees, if the weather prove frosty, as soon as they have cast their leaves. Cover late crops of grapes on hot walls with woollen nets or mats, to prevent injury from frost. Store and lay up very carefully during the month all sorts of apples and pears, the longest keeping sorts not before the end of the month, if the weather be mild. A part of them may be placed in a close cellar.

Forcing.—Assist hot-beds and pits with fresh linings, to keep up the declining heat of such beds as have not ripened off their crops. Give abundance of air in good weather. Gradually lower the heat of the pinery.

Dress vines and peaches; clean and repair the forcing houses and their flues.

Greenhouse.—Replace all sorts of greenhouse plants. Fill the pits with pots of stocks, mignonette, and hardy annuals for planting out in spring, along with many of the more hardy sorts of greenhouse plants. The whole ought to be thoroughly ventilated, except in frosty weather. Begin to force roses, hyacinths, and a few other bulbs, for winter and early spring decoration.

Flower Garden.—Sow a few pots of hardy annuals in a frame, or on a sheltered border, for spring use, as directed for August.

Plant the greater part of the common border bulbs about the end of the month, with a few anemonies for early flowering. Transplant strong plants of biennials and perennials to their final situations.

Protect alpine plants, stage auricules, and carnations with glass frames; half-hardy greenhouse plants, such as fuschsias, &c. about the end of the month, with coverings of broom or spruce-fir, preferring the latter. Take up, dry, and store dahlias and tigridia tubers in the end of the month; pot lobelias from the open borders.

Transplant all sorts of hardy evergreens and shrubs, especially in dry soils, giving abundance of water. Put in cuttings of all sorts of evergreens, &c.

November.

Kitchen Garden.—Sow early from pease and mazagan beans, in the second week, for an early crop. Protect endive, celery, artichoke, seakale, with stable-litter or ferns; mulch asparagus with hot-bed dung; take up endive, late cauliflower, early broccoli, and lettuces, and lay them in an open shed, or in old cucumber and melon pits, which will protect them from frost, and afford a supply during winter. Force rhubarb and seakale in the open border, under boxes or cases, surrounded and covered with well-fermented stable dung. Plant all sorts of fruit trees in fine weather, giving an abundant supply of water to settle the earth about the roots. Commence and carry on the various operations of pruning and nailing when the weather may permit. Take off such late sorts of apples and pears as may remain on the trees, and lay them carefully past in the fruit-room; which place will require frequent examination, and the removal of all decayed fruit.

Forcing and Greenhouse.—In hot-beds and pits keep up the requisite degree of heat by frequent additions to the linings. Cucumbers and pines, on hot-beds, will require more than ordinary attention, to prevent them damping off from too much moisture. Where a circulation of hot water in pipes is employed for heating, the necessary temperature and dryness are much more under the control of the gardener. Force asparagus, rhubarb, and seakale, in the mushroom-house or pits.

In the forcing-houses, prune and train the trees; dig and dress the borders of such houses as have not been already done. Continue the forcing of roses, hyacinths, &c. The directions for the greenhouse and conservatory in January apply also to this month generally.

Flower Garden, &c.—Plant dried tubers of border flowers, but the finer sorts had better be deferred till spring. Protect such half-hardy plants as were not sheltered last month. Plant deciduous trees and shrubs as long as the weather continues favourable. Dig and dress such flower borders and shrubberies as may now be cleared of annuals and the stems of herbaceous plants.

December.

Kitchen and Fruit Garden.—Sow a few pease and beans, as in November. Very few operations can be carried on during this month, with the exception of trenching and digging in dry weather.

Plant all sorts of fruit trees in mild weather. Proceed with pruning and nailing wall-trees, whenever an opportunity occurs. Examine the fruit-room every week, removing the fruit found in a state of decay.

Forcing, &c.—The same degree of attention to hot-beds and pits will be necessary as in the last month. Continue the forcing of asparagus, rhubarb, and sea-kale, in pits and in the mushroom house.

Proceed with the usual routine of culture commenced last month, making the necessary preparations to begin forcing by the last week of this, or the first of next month.

Flower Garden, &c.—The directions for last month will be found equally applicable to this. Rake and sweep leaves from lawns and gravel-walks, repairing the latter as occasion may require.

HOSANNA, in the Hebrew ceremonies, a prayer which was rehearsed on the several days of the feast of tabernacles. It was so called, because in it was frequently repeated the word הרשענא, *serva nunc*, or *serva precor*, save us now; or, save us, we pray. There were different hosannas, called by the Jews *hoschannoth*, that is, the *hosannas*. Some were rehearsed on the first day, others on the second, and so on, and they were called *hosanna* of the first day, *hosanna* of the second day, and so of the others.

Hosanna Rabba, or *Grand Hosanna*, is a name given to the feast of tabernacles, which lasted eight days, during the course of which they frequently invoked the assistance of God, the forgiveness of their sins, and his blessing on the new year, and for this purpose made great use of the hoschannoth, or prayers above mentioned. The Jews also applied the term *hosanna rabba*, in a more peculiar manner, to the seventh day of the feast of tabernacles, because on that day they in an especial manner invoked the divine blessing.

HOSEA, the first in number of the minor Hebrew prophets, as arranged in the Hebrew and Greek Bibles, although probably the third in chronological order. He was the son of Beeri; but it is uncertain to what tribe he belonged. He prophesied in the reigns of Uzziah, Jotham, Ahaz, and Hezekiah, kings of Judah, and in the time of Jeroboam, king of Israel. If he uttered predictions during sixty-six years, that is, between 790 and 724 before Christ, then he discharged the office of a sacred seer eight years during the reign of Jeroboam II. thirty-three in that of Uzziah, during the entire reigns of Jotham and Ahaz, and three years under the reign of Hezekiah; but he could not have survived the taking of Samaria. He reproved the vices of kings as well as their subjects, mixing threatenings of divine vengeance with promises of pardon in case of repentance. His style is concise and sententious, and his comparisons are short and lively. He is sometimes distinguished by great force of expression, has many beautiful passages, and in some parts is truly sublime. Dr Newcome was of opinion that the chief difficulty in understanding this prophet is owing to the corrupt readings which disfigure the printed text; and these he freely corrected from the collations of Dr Kennicott. On the other hand, Dr Horsley protests earnestly against Dr Newcome's opinion, declaring that the corruptions can be no cause of obscurity; but we must leave it to our readers to determine which of these great men is in the right, from an attentive perusal of their own works, assured that they will decide in favour of him who furnishes the best helps for understanding the prophet.

HOSPINIAN, Rodolphus, one of the greatest writers that Switzerland has given birth to. He was born in 1547, at Altorf, near Zurich, obtained the freedom of Zurich, and was made provisor of the abbey-school. Notwithstanding this employment, he undertook a work of vast extent, being a History of the Errors of Popery. Though he could not complete this work according to the plan which he had formed, he published a considerable part of it; whilst his treatise on the Eucharist, and another work called *Concordia Discors*, exceedingly exasperated the Lutherans. He did not reply to them; but turning his arms against the Jesuits, published *Historia Jesuitica*. These writings gained him preferment; he was appointed archdeacon of Caroline church, and then minister of the abbey-church. He died in 1626; and an edition of his works was published at Geneva, 1681, in seven volumes folio.

HOSPITAL, popularly Spittal, a place or building erected, out of charity, for the reception and support of the poor, aged, infirm, sick, and otherwise helpless. The word is formed from the Latin *hospes*, host, stranger. See Host.

In the early ages of the church, the bishop had the immediate charge of all the poor, both healthy and diseased, as also of widows, orphans, strangers, and others. When the churches came to have fixed revenues allotted to them, it was decreed that at least one fourth part of these should go to the relief of the poor; and to provide for them the more commodiously, houses of charity were built, which were afterwards denominated *hospitals*. They were governed wholly by the priests and deacons, under the inspection of the bishop. But in course of time, separate revenues were assigned for the hospitals; and particular persons, from motives of piety and charity, gave lands and money for erecting hospitals. When the church discipline began to relax, the priests, who till then had been the administrators of hospitals, converted them into a sort of benefices, which they held at pleasure, without accounting to any body, reserving the greater part of the income to their own use, so that the intentions of the founders were in a great measure frustrated. To remove this abuse, the council of Vienne expressly prohibited the giving any hospital to secular priests in the way of a benefice; and directed the administration of these establishments to be committed to sufficient and responsible laymen, who should take an oath, like that of tutors, for the faithful discharge of its duties, and be accountable to the ordinaries. This decree was executed and confirmed by the council of Trent.

In Britain hospitals are buildings properly endowed, or otherwise supported by charitable contributions, for the reception and support of the poor, aged, infirm, sick, or helpless.

HOSPITAL, or Hôpital, Michel de l', chancellor of France, and one of the most illustrious magistrates of modern times, was born at Aigueperse, in Auvergne, in the year 1505. His father, John de l'Hôpital, who was at once physician and counsellor to the Constable of Bourbon, sent him to study law, first at Toulouse, and afterwards at Padua, the legal school of which then enjoyed great celebrity. In that age jurisprudence was the principal science cultivated, and no one could aspire to any employment without having studied it profoundly. L'Hôpital, although he had already acquired the elements of this science in France, spent six years at Padua in improving himself therein; he also applied himself to the study of the belles-lettres, in which he made rapid advances, and at the same time cultivated the Greek and the Latin languages, with which he rendered himself perfectly familiar. Having completed his studies, and finding his prospects clouded by the death of the Cardinal de Grammont, who had induced him to return to France, and upon whose credit and influence he had founded his hopes of preferment, he entered himself of the bar at Paris. In this profession, his merit and virtue were soon appreciated. At the end of three years, John Morin, criminal lieutenant, a person famous in the martyrology of the Protestants, on account of the severity with which he enforced the laws enacted against them, gave L'Hôpital his daughter in marriage, and at the same time conferred upon him the office of counsellor to the parliament of Paris as her dowry.

In this situation, which he held during twelve years, the toleration he displayed formed a remarkable contrast to the unrelenting severity by which his father-in-law had rendered himself but too celebrated. When L'Hôpital entered the parliament, that once illustrious body had much degenerated, owing to the venality which the misfortunes of the time had forced Francis I. to introduce, or at least to overlook. A witness of this corruption, L'Hôpital deplored its consequences, and, in concert with some old magistrates who still remained, endeavoured to set an example of assiduity and application, to a crowd of inexperienced young men, who, by venality, had obtained admission into the parliament, and who had no other title to that honour but the money they had paid for it. L'Hôpital was long cited as a model in the magistracy. He made it a rule to listen with patience, to interrupt no one, to express himself as concisely as possible, and to oppose all unnecessary delays; he was also punctual in his attendance in court, where he generally remained until the business of the day had been regularly gone through, and always rose with reluctance, however late, if any portion of it remained unattended to. In short, he was a laborious and conscientious judge, who to great talents united the most steady and persevering industry. The vacations made no material change in his way of life; his pursuits were indeed different, but his application was the same; the perusal of the great writers of antiquity, the study of French history, and the reading of the Holy Scriptures, each in its turn formed the occupation of his leisure time. "There is nothing frivolous in my amusements," says he, in one of his letters; "sometimes Xenophon is the companion of my walks; sometimes the divine Plato regales me with the discourses of Socrates. History and poetry have their turns; but my chief delight is in the sacred writings."

The next appointment which L'Hôpital received was that conferred upon him by Henri II. of envoy or ambassador to the council of Trent, which was then sitting at Bologna. But having soon grown tired of the inactivity to which he found himself reduced, he was, at his own desire, recalled, and, upon his return, experienced some coldness on the part of the court, which did not altogether relish his evident disinclination to assist in the proceedings of that famous council. This obscuration, however, proved only temporary, for ere long he was restored to the royal favour, and appointed master of the requests. Nor did his promotion stop here. In the beginning of 1554, he was constituted director and superintendent of the royal finances in the chamber of accounts. At this time the finances required a guardian at once vigilant and faithful. Enormous abuses prevailed in the whole fiscal administration. On the one hand there existed profusion without limits, and on the other malversation without shame. Scarcely a third, or even a fourth part of the sums collected, ever reached the royal treasury; the people were exposed to the most grinding exactions, yet the revenue was in a state of gradual decline. To put an end to these disorders, L'Hôpital revived the ancient laws which had fallen into desuetude; he struck terror into defaulters by some examples of wholesome severity; he refused to sanction any expenditure except for the immediate purposes of the state; he defied the enmity of that numerous and vindictive class whose dishonest gains he had destroyed; and he acted with so much personal disinterestedness, that, after having been five years in office, he was unable to give a portion to his daughter, and the deficiency was supplied by the liberality of the sovereign.

After the fatal accident which, in 1559, put an end to the life of the king, the Cardinal de Lorraine, then at the head of affairs, introduced L'Hôpital into the council of state; but as one of the articles of the treaty of Chateau-Cambrésis had provided that the Duchess of Berri, his benefactress, should espouse Emanuel-Philibert, Duke of Savoy, he was appointed to conduct that princess into Piedmont, whither he attended her in the capacity of chancellor. The distracted situation of France, however, soon made it necessary to recall a man of such undaunted firmness and inflexible integrity. In the midst of faction, turbulence, and confusion, when the passions of men appeared, like the evil spirits, to have been for a season unchained, he was advanced to the office of chancellor of France, and in this elevated station conducted himself like a philosopher and a hero, superior alike to weakness and to fear. At this period the destruction of the Protestants had been determined on; it was resolved to leave them no alternative but abjuration or death; and it was even in contemplation to establish in France the redoubtable tribunal of the inquisition. The new chancellor durst not attack this project in front, without compromising himself with the governing party; but he sought indirectly to defeat the odious design, and by the edict of Romorantin, which declared the crime of heresy to be cognisable only by the ecclesiastical judge, he ultimately accomplished his beneficent design, and thus decided the clergy to abandon all idea of establishing the inquisition, which, they knew, would be powerless when deprived of the aid of the secular arm. Upon all occasions, indeed, he was the advocate of mercy and reconciliation, and a declared enemy to persecution on account of religion; and hence the more bigoted Romanists, offended at his wisdom and moderation, accused him of being a concealed Protestant, forgetting that by such suspicions and accusations they paid the highest compliments to the spirit of that faith which they were so desirous to eradicate. With a man of such character, ability, and firmness at the head of affairs, it was hopeless to attempt to carry through the violent measures which were already contemplated; yet when the question of giving him a successor came to be seriously agitated, Catherine of Medicis found herself involved in very great perplexity. The ancient relations of L'Hôpital with the House of Lorraine; the estimation in which he was universally held, his known love of his country, which, in his mind, absorbed all other affections; and the difficulty of finding any one to fill his place, who would not sink into insignificance or contempt in comparison with this truly great man—were serious obstacles to his removal: but as nothing could induce him to abandon or change the pacific character of his measures, all other considerations were at length disregarded, and the queen excluded him from the council of war, upon which he immediately withdrew to his country-house at Vignay, near Estampes.

His exclusion from the council was accompanied with insult. The Constable of Montmorency told him that a man of his profession, a civilian, ought not to intermeddle in what related to war. "That is a subject," said the constable, "on which you are not qualified to give advice." "True," replied the chancellor, "I do not know how to make war, but *I know when it is necessary.*" Several days after his retirement from office, when the seals were demanded of him, he resigned them without regret, observing that the affairs of the world were too corrupt for him to meddle with them. He spent his time in lettered ease, amusing himself with writing Latin poetry, and enjoying the society of some select friends, until his peace was broken by the bloody tragedy of St Bartholomew, which, with his usual sagacity, he had foreseen. Of this barbarous and inexpiable massacre the judgment he pronounced has been ratified by posterity. He was himself near becoming one of its victims. The inhabitants of the country had risen, and were devastating the fields, and dragging the farmers in chains towards the city. But the queen, anxious about his fate, sent a detachment of cavalry for his protection. The sudden apparition of this troop, whose destination was unknown, produced great consternation in his house, which was open on all sides. He was asked by the inmates if they would close the gates. "No, no," said he; "if the small gate will not admit them, throw open the large one." When informed that the persons who prepared the lists of proscription had pardoned him the opposition which he had always given to their projects; "I did not know," replied he coldly, "that I had done any thing to deserve either pardon or death." But what most deeply affected L'Hôpital on this mournful occasion, was the danger to which his daughter, who happened to be in Paris, was in consequence exposed. She was saved by the interference of

Anne d'Este, duchess of Guise, whom L'Hôpital thanked for this signal service, in an epistle overflowing with the warmest feelings of paternal gratitude. These cruel events, however, deeply affected his health and spirits, and he died at Vignay, on the 13th of March 1573, at the age of sixty-eight, and less than one year after the massacre.

"L'Hôpital," says Brantôme, "was the greatest, worthiest, and most learned chancellor that was ever known in France. His large white beard, pale countenance, and austere manner, made all who saw him think they beheld a true portrait of St Jerome, and, in fact, he was called St Jerome by the courtiers. All orders of men feared him, particularly the members of the courts of justice; and when he examined them on their lives, their discharge of their duties, their capacities or their knowledge, and particularly when he examined candidates for offices, and found them deficient, he made them feel it. He was profoundly versed in polite learning, very eloquent, and an excellent poet. His severity was never ill natured; he made due allowance for the imperfections of human nature; he was always equal and firm. After his death, his very enemies acknowledged that he was the greatest magistrate whom France had known, and that they did not expect to see such another." The productions of L'Hôpital are, 1. Latin Poems; 2. Speeches delivered at the Meeting of the States at Orleans; 3. *Mémoires, contenant plusieurs Traités de Paix*, &c., from 1551 to 1560, Cologne, 1672, in 12mo. A work which he had undertaken on law is lost; and it is said that he had also projected a history of his own time, on the model of the ancient historians; but of this no part appears to have been executed. In 1807, M. Bernardi published his *Essai sur la Vie, les Ecrits, et les Loix de Michel de l'Hôpital*, in one volume 8vo, from which and other documents Mr Charles Butler published his Essay on the Life of L'Hôpital, principally with the view of exhibiting him as a friend of toleration. (A.)

HOSPITAL, *William-Francis-Antony, Marquis of*, an eminent French mathematician, was born of an ancient family in 1661. He was a geometrician almost from his infancy; for one day being at the Duke of Rohan's, where some able mathematicians were speaking of a problem of Pascal's which appeared to them extremely difficult, he ventured to say that he believed he could solve it. They were amazed at such presumption in a boy of fifteen, for he was then no more; nevertheless, in a few days he sent them the solution. He entered early into the army, and rose to be a captain of horse; but being extremely shortsighted, and exposed on that account to perpetual inconveniences and errors, he at length quitted the army, and applied himself entirely to his favourite pursuit. He contracted a friendship for Malebranche, whose opinion he followed upon all occasions. In 1693 he was received as an honorary member of the Academy of Sciences at Paris; and he published a work upon Sir Isaac Newton's calculations, entitled *L'Analyse des Infinimens Petits*. He was the first in France who wrote upon this subject, and on this account was regarded almost as a prodigy. He engaged afterwards in another work of the mathematical kind, in which he included *Les Sections Coniques, les Lieux Géométriques, la Construction des Equations, et Une Théorie des Courbes Mécaniques;* but a little before he had finished it, he was seized with a fever, of which he died on the 2d of February 1704, at the age of forty-three. It was published after his death.

HOSPITALITY, the practice of entertaining strangers. Dr Robertson, speaking of the middle ages, says, "Among people whose manners are simple, and who are seldom visited by strangers, hospitality is a virtue of the first rank. This duty of hospitality was so necessary in that state of society which took place during the middle ages, that it was not considered as one of those virtues which men may practise or not, according to the temper of their minds and the generosity of their hearts. Hospitality was enforced by statutes, and those who neglected the duty were liable to punishment. The laws of the Salvi ordained that the moveables of an inhospitable person should be confiscated, and his house burnt. They were even so solicitous for the entertainment of strangers, that they permitted the landlord to steal for the support of his guest."

The hospitality of our British ancestors, particularly of the great and opulent barons, has been much admired, and considered as a certain proof of nobleness and generosity of spirit. The fact indeed is well attested. The castles of the powerful barons were capacious palaces, daily crowded with numerous retainers, who were always welcome to plentiful tables. They had their privy councillors, their treasurers, marshals, constables, stewards, secretaries, chaplains, heralds, pursuivants, pages, henchmen or guards, trumpeters, minstrels, and, in a word, all the officers of a royal court. The etiquette of their families was an exact copy of that of the royal household; and some of them lived in a degree of pomp and splendour little inferior to that of the greatest kings. Richard Neville, earl of Warwick, we are told, "was ever had in great favour of the commons of the land, because of the exceeding household which he daily kept in all countries wherever he sojourned or lay; and when he came to London, he held such an house, that six oxen were eaten at a breakfast, and every tavern was full of his meat." The Earls of Douglas in Scotland, before the fall of that great family, rivalled or rather exceeded their sovereigns in pomp and profuse hospitality. But it is highly probable these great chieftains were prompted to indulge this style of living by a desire of increasing the number and attachment of their retainers, on which, in those turbulent times, their dignity, and even their safety, depended, as much as to the innate generosity of their tempers. Those retainers did not constantly reside in the families of their lords; but they wore their liveries and badges, frequently feasted in their halls, swelled their retinues on all great solemnities, attended them in their journeys, and followed them into the field of battle. Some powerful chieftains had constantly at their command so great a number of these retainers, that, setting the laws at defiance, they became formidable to their sovereigns, and terrible to their fellow-subjects; and several laws were made against giving and receiving liveries. But these laws produced little effect at this period.

Hospitality was not confined to the great and opulent, but was practised rather more than it is at present by persons in the middle and lower ranks of life. But this was owing to necessity, arising from the scarcity of inns, which obliged travellers and strangers to apply to private persons for lodging and entertainment; and those who received them hospitably acquired a right to a similar reception. This was evidently the case in Scotland in the first part of this period. In the year 1424, James I. procured the following act of parliament:—"It is ordanit, That in all burrow townis, and throuchfairis quhair commoun passages ar, that thair be ordanit hostillaries and resettis, havand stables and chalmers; and that men find with thame bread and aill, and all uther fude, alsweil for horse as men, for resonable price." But travellers had been so long accustomed to lodge in private houses, that these public inns were quite neglected; and those who kept them presented a petition to parliament, complaining, "That the liegis travelland in the realme, quhen they cum to burrowis and throuchfairis, herbreis thame not in hostillaries, bot with thair acquaintance and freindis." This produced an act prohibiting travellers to lodge in private houses where there were hostelries, under the penalty of forty shillings, and subjecting those who lodged them to the same penalty.

The inhabitants of the Highlands of Scotland and the Western Isles were anciently remarkable for their hospitality to strangers, and still happily retain, in no inconsiderable degree, the same kindly disposition.

HOSPITALLERS, Hospitalarii, an order of religious knights, who built at Jerusalem an hospital, in which pilgrims were received. To these Pope Clement V. transferred the effects and revenues of the Templars, whom, by a council held at Vienne, he suppressed for their numerous and flagrant misdemeanours. These hospitallers, otherwise called knights of St John of Jerusalem, are the same with those who were latterly called knights of Malta.

HOSPITIUM, a term used in old writers either for an inn or a monastery, built for the reception of strangers and travellers.

HOSPODAR, a title borne by the princes of Moldavia and Wallachia, who used to receive the investiture of their principalities from the grand seignior. He gave them a vest and standard; they were under his protection, and obliged to serve him; and he even sometimes deposed them; but in other respects they were absolute sovereigns within their own dominions. But since the treaty of Adrianople, concluded between Russia and Turkey in 1829, the former power has acquired an ascendency in these principalities, and obtained a complete control over the nomination of the hospodars.

HOSSEEPOOR, a town of Hindustan, province of Bahar, eighty-two miles north-west from Patna. Long. 84. 17. E. Lat. 26. 25. N.

HOSSEIN-ABDAUL, a town of Hindustan, province of Lahore, situated thirty miles east of the Indus. It is the frontier town of the Afghans, and has been a frequent object of contention between them and the Sikhs. Long. 71. 43. E. Lat. 33. N.

HOSSOBETTA, a town in the south of Hindustan, and province of North Canara. The principal inhabitants consist of Concanies, or the descendants of the natives of the Concan, who, according to the account of Dr Buchanan, fled thither from the Portuguese settlement of Goa, in order to avoid the persecutions of the Portuguese Catholics, who were desirous to convert them to the Christian faith. Long. 75. E. Lat. 12. 42. N.

HOSSO-DURGA, a small town of Hindustan, in the province of South Canara. It possesses a fort and a temple, which is served by a few Puttar Brahmins, the chief inhabitants of the place. The fort is large and well built, with round bastions, which render it more defensible than the forts in India with square bastions generally are. The surrounding country is overgrown with wood, and but thinly inhabited, consisting, like the rest of Malabar, of low hills and narrow valleys alternately.

HOST, Hospes, a term of mutual relation, applied both to a person who lodges and entertains another, and to the person thus lodged. It is formed from the Latin *hospes*, which according to some, was thus called *quasi hostium* or *ostium petens, ostium* having anciently been written with an aspirate. Thus the innkeeper says, he has a good *host*, in speaking of the traveller who lodges with him; and the traveller, again, says he has a kind *host*, in speaking of his landlord.

It must be observed, however, that it was the custom amongst the ancients, when any stranger asked lodging, for the master of the house, and the stranger, each of them to set a foot on their own side of the threshhold, and swear they would neither of them do any harm to the other. It was this ceremony which raised so much horror against those who violated the law or right of hospitality on either side, inasmuch as they were looked upon as perjured.

Instead of *hospes*, the ancient Latins called it *hostis*, as Cicero himself informs us; though, in course of time, *hostis* came to signify an enemy, so much had the notion of hospitality degenerated.

Host is also used by way of abbreviation for *hostia*, a victim or sacrifice offered to the Deity. In this sense, *host* is more immediately understood of the person of the Word Incarnate, who was offered up an host or *hostia* to the Father on the cross for the sins of mankind.

Host, in the church of Rome, a name given to the elements used in the eucharist, or rather to the consecrated wafer, which they pretend to offer up every day as a new host or sacrifice for the sins of mankind.

HOSTAGE, a person given up to an enemy as a security for the performance of the articles of a treaty.

HOSTIA, Host, in *Antiquity*, a victim offered in sacrifice to a deity.

The word is formed from *hostis*, enemy, it being the custom to offer up a sacrifice before they joined battle, to render the gods propitious, or, after the battle was over, to return them thanks. Some choose to derive the word from *hostio*, the same as *ferio*, I strike. Isidore remarks on this word, that the name *hostiæ* was given to those sacrifices which they offered before they marched to attack an enemy (*antiquam ad hostem pergerent*); in contradistinction to *victimæ*, which were properly those offered after the victory.

Hostia also signified the lesser sorts of sacrifice, and *victima* the larger. Aulus Gellius says, that every priest, indifferently, might sacrifice the *hostia*, but that the *victima* could be offered by none but the conqueror himself. After all, however, we find these two words promiscuously used, one for the other, by ancient writers. We read of many kinds of *hostiæ*, as *hostiæ puræ*, which were pigs or lambs ten days old; *hostiæ præcidaneæ*, sacrifices offered the day before a solemn feast; *hostiæ bidentes*, sacrifices of sheep or other animals of two years old; *hostiæ eximiæ*, a sacrifice of the flower of the flock; *hostiæ succedaneæ*, sacrifices offered after others which had exhibited some ill omen; *hostiæ ambarvales*, victims sacrificed after having been solemnly led round the fields at the *ambarvalia; hostiæ amburbiales*, victims slain after the *amburbium; hostiæ caneares* or *caviares*, victims sacrificed every fifth year by the college of pontiffs, in which they offered the part of the tail called *caviar; hostiæ prodigiæ*, sacrifices in which the fire consumed all, and left nothing for the priests; *hostiæ piaculares*, expiatory sacrifices; *hostiæ ambegnæ* or *ambiegnæ*, sacrifices of cows or sheep that had brought forth twins; *hostiæ harugæ*, victims offered to predict future events from; *hostiæ mediales*, black victims offered at noon.

HOSTILITY, the action of an enemy, or a state of warfare. The word is low Latin, *hostilitas*, formed from the primitive word *hostis*, which signifies enemy, and which anciently signified stranger, *hospes*.

HOT-Beds, in *Gardening*, beds made with fresh horse-dung or tanners' bark, and covered with glasses to defend them from cold winds. See Horticulture.

HOT-House. See Horticulture.

HOTEL, a French term, anciently signifying a house or dwelling-place. It was afterwards used to signify the palaces or houses of the king, princes, and great lords.

Hotel likewise means a large inn, or a large lodging-house ready furnished.

HOTTENTOTS, the original inhabitants of Cape Colony, and other places in the southern angle of Africa. They are divided into several tribes, but their mental and physical characteristics are the same in all. They have been already fully described in the articles Africa and Good Hope, Cape of, which see.

HOTTINGER, John Henry, one of the most learned and eminent of the Protestant divines of Switzerland, was born at Zurich in the year 1620. At an early age he discovered an invincible propensity to learning, and acquired with astonishing facility the knowledge of languages.

The trustees of the schools had their attention attracted towards Hottinger by his amazing progress in the knowledge of the Hebrew, Greek, and Latin, and they determined to send him to foreign universities at the public expense. In 1638 he studied for a short time at Geneva under the celebrated Frederick Spanheim, and went afterwards to France. He next visited Holland and Flanders, and became a student in the university of Groningen, where he attended the theological lectures of Francis Gomar and Professor Alting, and studied the Arabic language under Professor Pasor. Being anxious, however, to enjoy still greater advantages than this situation afforded, he went to Leyden, where he became tutor to the children of Professor Golius, whose knowledge of oriental languages was at that time unrivalled. By his instructions and those of a Turk then at Leyden, Hottinger acquired an extensive knowledge of the Arabic, and Golius permitted him to copy many of the Arabic manuscripts which he had in his possession. In 1641 he was chosen chaplain to the embassy of the states-general to Constantinople; but the magistrates of Zurich would not suffer him to accept of it, resolving that his talents should be exerted for the glory and the benefit of their own public schools. They permitted him to visit England prior to his return home, where he contracted habits of intimacy with some of the most distinguished literary characters. As soon as he returned to Zurich, he was appointed professor of church history, when not more than twenty-two years of age; and when twenty-three, he was chosen professor of catechetical divinity and oriental languages. About this period he married, and began his career as an author, in which he persevered for twenty years with the most astonishing industry. In 1653 he was appointed professor of rhetoric, and professor extraordinary of the divinity of the Old Testament, and of controversial theology.

About this time Hottinger became so justly celebrated as a man of uncommon erudition, that his aid was earnestly requested by the elector palatine to restore the fame of the university of Heidelberg. The magistrates of Zurich consented to lend him for three years. At Heidelberg he was named professor of divinity, principal, ecclesiastical counsellor, and rector; and he wrote in favour of the reunion of Lutherans and Calvinists; but he had no better success than his predecessors who had made the same attempt. He continued at Heidelberg, by permission of the magistrates of Zurich, till the year 1661. On his return home he was chosen president of the commissioners who were appointed to revise the German translation of the Bible. Though requested to accept of professorships from the magistrates of Deventer, the landgrave of Hesse, and the magistrates of Amsterdam and Bremen, the love of his country induced him to reject all these offers. He was offered the divinity chair at Leyden in 1667; but the magistrates would not part with him. This made the Dutch request him as a loan, to which the magistrates agreed, from their respect for the states of Holland; but whilst making preparations for his departure, he was unfortunately drowned in the river which runs through Zurich, when on his way to an estate of his own, about six miles from that city.

Dr Hottinger was a man of extraordinary abilities, both natural and acquired, having few equals in his knowledge of oriental languages and the antiquities of the church. He had a most retentive memory, and his literary industry was almost unexampled. His life was comparatively short, being only forty-seven when he found a watery grave; yet he was the author of no fewer than forty volumes on different subjects. He is frequently inaccurate, owing to the astonishing rapidity with which he wrote. His principal works are, 1. Exercitationes Anti-Morinianæ de Pentateucho Samaritano, Zurich, 1644, in 4to; 2. Erotematum Linguæ Sanctæ libri duo, cum Apendice Aphorismorum, ibid. 1647; 3. Thesaurus Philologicus, seu Clavis Scripturæ qua quidquid fere Orientalium, Hebræorum maxime et Arabum habent monumenta de Religione ejusque variis speciebus, Judaïsmo, Samaritanismo, Muhamedismo, Gentilismo, &c. ibid. 1649; 4. Historia Ecclesiastica Novi Testamenti, in nine parts, 1651–1667; 5. Historia Orientalis ex variis Monumentis Collecta, ibid. 1651, in 4to; 6. Grammaticæ Chaldæo-Syriacæ libri duo, ibid. 1652; 7. Analecta Historico-Theologica, octo Dissertationibus proposita; 8. Dissertationum miscellanearum Pentas, ibid. 1654, in 8vo; 9. Dissertatio de Subsidiis Analyseos Sacræ, ubi prolixe de Sensu Verborum Institutionis Cœnæ Dominicæ, ibid. 1654, in 8vo; 10. Juris Hebræorum leges 261, juxta Legis Mosaïcæ ordinem ac seriem depromptæ; 11. Smegma Orientale sordibus barbarismi contemptui præsertim Linguarum Orientalium appositum, Heidelberg, 1657, in 4to; 12. Grammatica Ling. Hebr. Chald. Syr. et Arabicæ Harmonica, ibid. 1657; 13. Cippi Hebraïci, ibid. 1659, in 8vo; 14. Primitiæ Heidelbergenses, ibid. 1659; 15. Dissert. Theolog. Philolog. fasciculus, ibid. 1660; 16. Etymologicon Orientale, sive Lexicon Harmonicon Heptaglotton, 1661, in 4to; 17. Epitome utriusque Juris Judaici, Aphorismis Maimonides exhibita, ibid. 1661; 18. Compendium Theologiæ Christianæ Ecclesiarum Orientalium, Syrorum cum primis, Æthiopum, Arabum, et Ægyptiorum; 19. Compendium Theatri Ismaelitici sive Saracenici, ibid. 1662, in 8vo; 20. Bibliothecarius tripartitus, Zurich, 1664, in 4to.

HOUBRAKEN, Jacob, an eminent engraver, was the son of Arnold Houbraken, a native of Holland, and born on the 25th of December 1698. By whom he was instructed in engraving we are not informed, but he is supposed to have been initiated in the principles of the art by his father, and to have studied the portraits of Edelink, especially that of Lebrun, which is usually prefixed to the engravings of Gerard Audran from the battles of Alexander. For some time he worked in obscurity without obtaining either profit or fame, and he had attained the meridian of life before he engaged in the undertaking by which he is best known; a work founded on a plan of George Vertue, who proposed to give sets or classes of eminent men, though the design was afterwards adopted by others, and thus taken out of the hands of the projector. The persons who undertook and brought to a conclusion this great national work were the Knaptons, booksellers, who, encouraged by the success of Rapin's History of England, employed both Vertue and Houbraken, but chiefly the latter. Some of Houbraken's heads were carelessly executed, especially those of the moderns; but others display a wonderful union of softness and freedom, with good drawing and a masterly determination of the features, such as we observe in the works of Nanteuil, Edelink, and Drevet. From his solicitude to avoid the appearance of an outline, he frequently neglected the little sharpnesses of light and shadow which appear in nature, and, like the accidental semitones in music, excite a pleasing sensation in the mind, in proportion as the variation is judiciously managed. For want of attention to this essential beauty, many of his productions have a hazy appearance, and do not strike the eye with the force which might be expected from the excellence of the engraving. Houbraken lived to a good old age, and died at Amsterdam in 1780. (A.)

HOUGHTON le Spring, a town of the ward of Easington, in the county of Durham, 266 miles from London, and seven from Durham. There is a well-endowed classical school, founded by a former rector; and the livery is a very valuable one, in the gift of the bishop. The inhabitants amounted in 1801 to 996, in 1811 to 1356, in 1821 to 2905, and in 1831 to 3917.

HOUND.

FROM the combination of various causes, the history of no animal is more interesting than that of the dog. First, his intimate association with man, not only as his valuable servant and protector, but as his constant and faithful companion throughout all the vicissitudes of life. Secondly, from his natural endowments, not consisting solely in the exquisite delicacy of one individual sense, that fineness of olfactory nerve by which the earth and air send forth showers of perfumes; not merely combining memory with reflection that soars above instinctive preservation or self-enjoyment; but qualities of the mind that absolutely stagger us in the contemplation of them, and which we can alone account for in the gradation existing in that wonderful system which (by different links of one vast chain, extending from the first to the last of all things, till it forms a perfect whole) is placed, as Professor Harwood elegantly expresses it, "in the doubtful confines of the material and spiritual worlds." It might have been instinct that enabled Ulysses's dog to recognize him on his re-landing in Ithaca, after an absence which must have set the powers of memory at defiance; and he recognized him with all the acuteness and affection which instinct boasts; *but what caused him to expire at his feet on the sudden dawn of unexpected happiness?* The heart of man could go no further than this; and although perhaps the poet's fiction is only present to us in this instance, by what name can we call those tender affections, those sincere attachments, those personal considerations, which we ourselves have witnessed in these faithful creatures towards human kind? Virtue alone is too cold a term, as almost every good quality to be found in animated nature is to be found here; and when we reflect upon the miserable existence so often the lot of this kind-hearted animal in this world, and the more than uncertainty that, as Byron says, he will be

> "Denied in heaven the soul he held on earth,"

we cannot but feel regret that he should be without his reward. But yet this is a point not exactly decided upon by man; at least it has been considered as a fit subject for speculation by deep and able thinkers. Mr Locke, for example, doubted whether brutes survive the grave, because there is no hint given of it in revelation; but Dr Priestley thought, if the resurrection of the dead be within the proper course of nature, and there be something remaining of every organized body that death does not destroy, there will be reason to conclude that they will be benefited by it as well as ourselves. "The misery," says this forcible writer, and great moral philosopher, "some animals are exposed to in this life, may induce us to think that a merciful and just God will make them some recompense for it hereafter."

But no animal has met with more variety of respect shown towards him than the dog has. By the law of Moses he was declared unclean, and was held in great contempt by the Jews, as also by the Turks, and kept by both merely for the purposes of scavenging their streets. In every part of the sacred writings, as also in those of Greece and Rome, not only are images introduced from the works of nature, and metaphors drawn from the manners and economy of animals, but the names of them are applied to persons supposed to possess any of their respective qualities. Thus our Saviour, adopting this concise method, applies the word "dog" to men of odious character and violent temper; and, as with us at present, the term of reproach, "he was a son of a dog," was in common use among the Jews. The wife Abigail (1 Samuel, xxv. 3) "was a woman of good understanding, and of a beautiful countenance; but the man (Nabal) was churlish and evil in his doings, and *was of the house of Caleb.*" But this last, says an able expounder of the Scriptures, is not a proper name. Literally it is, "he was the son of a dog." On the other hand, the idolatrous Egyptians held the dog sacred, and worshipped him in their god Anubis, representing the form of a man with a dog's head, which Juvenal complains of in his fifteenth satire:

> "Oppida tota canem venerantur, nemo Dianam."

Anubis, says Strabo, is also the city of dogs, the capital of the Cynopolitan prefecture. "Those animals," says he, "are fed there on sacred aliments, and religion has decreed them a worship." This absurd adoration is confirmed by Diodorus Siculus and Herodotus; and Rome having adopted the ceremonies of Egypt, the Emperor Commodus, when celebrating the Isiac feasts, shaved his head, and himself carried the dog Anubis.

But to proceed to their origin and history. It has been justly remarked, that "all dogs whatsoever, even from the terrible Boar-dog to little Flora, were all one in the first creation;" and every virtue and faculty, size and shape, which we find or improve in every dog upon earth, were originally comprehended in the first parents of the species, nothing having remained constant but their natural conformation; and all the variety which we now behold in them is either the product of climate or the accidental effect of soil, food, or situation, and very frequently the issue alone of human care, curiosity, or caprice. This we take to be the case with other departments of the creation. For example, we only acknowledge two sorts of pigeons, the wild and the tame. Of the first there is but one, the œnas, or vinago of Ray. Of the last, the varieties are innumerable. The tame and the wild goose are likewise originally of the same species, the influence of domestication alone having caused the tame ones to differ from the parent stock. Notwithstanding, however, the efforts and effects of human industry and skill, there is fortunately a *ne plus ultra* in nature which cannot be passed; and as there is a distinct specific difference in all living creatures, a pigeon is still a pigeon, a goose a goose, and a dog remains a dog. Still, although no human device can add one new *species* to the works of the creation, and nature is still uniform in the main, as we have already observed, in our remarks on the horse, she is always ready to meet the demands of art, a fact beautifully set forth in these lines of *Hudibras*:—

> "How fair and sweet the planted rose,
> Beyond the wild in hedges grows!
> For without art the noblest seeds
> Of flowers degen'rate into weeds.
> How dull and rugged, ere 'tis ground
> And polish'd, is the diamond.
> Though Paradise were e'er so fair,
> It was not kept so without care:
> The whole world, without art and dress,
> Would be but one great wilderness;
> And mankind but a savage herd,
> For all that nature has conferr'd.
> This does but rough-hew and design,
> Leaves art to polish and refine."

We have good reason to believe that England (in a great measure from the congeniality of its climate) has long been famous for dogs, which, on the authority of Strabo (lib. iv. p. 199), were much sought after by all the surrounding nations. So high indeed in repute were British dogs amongst the Romans after the reduction of our island, not only for excellence in the chase, but fierceness in the combat, that an officer from that country was appointed to reside in the city of Winchester, for the express purpose of collecting and breeding them to supply the amphitheatre, as well as the imperial kennel, at Rome. Nor was this all. As a kind of earnest of our present celebrity in the various sports of the field, all the neighbouring countries, as Dr Campbell remarks, "have done justice to our dogs, adopted our terms and names into their language, received them thankfully as presents, and, when they have an opportunity, purchased them at a dear rate."[1] Thus we find, that when King Alfred requested Fulco, archbishop of Rheims, to send some learned ecclesiastics into England, he accompanied his letter with a present of several dogs, being the most valuable he could, in those times, bestow. The congeniality of our climate has contributed much to this excellence, as our dogs, hounds especially, are found to degenerate in most others; which Somerville alludes to in his poem of the Chase.

> "In thee alone, fair land of liberty,
> Is bred the perfect hound, in scent and speed
> As yet unrivall'd, while in other climes
> Their virtue fails, a weak degen'rate race."

We do not benefit much by research into ancient authors on the subject of dogs; for although they have been much written upon, and immortalised in song by Oppian, Claudian, Gratius, and others (Virgil says little about them), yet, from our ignorance of the sort of animal bred in their time, and the use they made of them, *as sportsmen*, we can draw no parallel between them and our own that would tend to a good purpose. No doubt the "canis *vestigator*" of Columella, and the "canis *odorus*" of Claudian, were of what we term a low-scenting sort, as the epithets applied to them signify; but it would be difficult to pronounce an opinion upon the καστόριαι, or the ἀλωπεκίδες, of Xenophon, although the characteristic properties of good hunting hounds are very well and accurately laid down by him in the third chapter of his Κυνηγετικος, as well as their defects in form, &c. equally clearly exposed; and his observations on these points might be perused with advantage by huntsmen of the present day.

Great encouragement has been given to the breeding of hounds in England by the various monarchs who have reigned over it. Henry II. was perhaps the first who made himself conspicuous in this department of the sportsman's occupation, being, as one of his historians says of him, "particularly curious in his hounds, that they should be fleet, well-tongued, and consonous." The last epithet is in reference to a property not only little regarded, but nearly lost now, namely, the deep tongue of the old English blood-hound, which Shakspeare alludes to in his celebrated description of those "of the Spartan kind:"

> "(So flewed, so sanded, and their heads are hung
> With ears that sweep away the morning dew.
> Crook-knee'd, and dewlapt, like Thessalian bulls;
> Slow in pursuit; but match'd in mouth like bells,
> Each under each:)"

which would now be considered a disgrace to any man's kennel, and we believe nowhere to be found, bearing the faintest resemblance to the picture drawn of them by this master-hand.

In Queen Elizabeth's time a classification was made by Dr Caius, physician to the queen, in his treatise *De Canibus Britannicis*, of the different kinds of dogs peculiar to Great Britain; but many of the names (the sleute or sluth hound of the Scotch, for example) having since become obsolete, they were again classed by Mr Daniel, in his *Rural Sports*, which work contains a full and satisfactory historical account of their origin, different crosses, &c. under the following genealogical heads:—Shepherd's Dog, Iceland Dog, Lapland Dog, Siberian Dog, Hound, Terrier, Large Spaniel, Small Spaniel, Water Dog, Small Water Dog, Bull Dog, Large Danish Dog, Irish Greyhound, English Greyhound, and Mastiff. Taplin, in his *Sporting Dictionary*, expresses his surprise that the Pointer is omitted; but we consider the Pointer as a dog of foreign extraction, and to our early ancestors certainly unknown.

The original stock from which English hounds have been bred would be very difficult to determine upon; but one thing is certain, namely, that the several sorts with which the country once abounded have been becoming fewer and fewer, in the course of the last hundred years, and now centre in three varieties, namely, the Fox-hound, the Harrier, and the Beagle. The stag-hound is gone, at least there is no pack of stag-hounds now kept in Great Britain, the last having been disposed of and sent abroad, soon after the stag hunting establishment in Devonshire was broken up, a few years ago. The beagle is also become rare; and otter-hounds, such as we may conclude the καστόριαι of Xenophon to have been, never existed in this country, the dog used in hunting the otter being the common harrier; and perhaps the parent of all, the majestic blood-hound, whose

> "Nostrils oft, if ancient fame sings true,
> Trace the sly felon through the tainted dew,"

is at present very thinly scattered, here and there only, at keepers' lodges in some of our royal forests. But we more than doubt whether a true specimen of the original English blood-hound exists in England at all at the present day; nor is this a matter of regret, as, unlike the rest of his species, his character is said to be that of decided enmity to man. Strabo describes an attack upon the Gauls by these animals, and likewise says they were purchased in Britain by the Celtæ, for the purposes of war, as well as those of the chase; but it is doubtful whether the most savage of this race would devour man without being trained to it, which we know that they were on a late horrible occasion, when, as stated in Rainsford's *History of St Domingo*, they were fed upon blood, and a figure representing a negro, containing blood and entrails of beasts, was the object they were led to pursue. In the West Indies, however, the blood-hound, under proper control, has been found useful in tracing runaway negroes, as the sluthhound of the Scotch was early applied to discover the haunts of robbers; and to the same purpose also on the confines of England and Wales, where the borderers preyed on the flocks and herds of their neighbours, whenever an opportunity offered. Of deer-stealers, who were so numerous a century or two ago, they were likewise the terror; and well might they have been so, for when once fairly laid upon the foot of one, they seldom failed to hunt up to him. But it is in the civil wars of our own country that blood-hounds are placed in the most conspicuous light, particularly as available to the operations of Wallace and Bruce; and the poetical historians of the two heroes allude to their services to their masters, as well as to the escapes they had from those of their various enemies.

The distinguishing features of the English blood-hound are, long, smooth, and pendulous ears, with a wide forehead, obtuse nose, expansive nostrils, and deep flewed, with an awfully deep but highly sonorous tongue. The prevailing colour is a reddish tan, darkening to the upper part, often with a mixture of black upon the back. In short, the deep-flewed southern hare-hound, now almost extinct in England, very nearly resembles the English bloodhound in form and colour; and a person may picture to himself the latter, by supposing an animal considerably larger than the old southern hound. In height he is from twenty-six to twenty-eight inches, and sometimes more. The blood-hound of the West Indies is also about the same height, but differs much in form. He has small, erect ears, the nose more pointed, and the hair and skin hard. His countenance is ill featured and ferocious; and although not so heavy as the English blood-hound, he is quite as muscular, and very active.

---

[1] Campbell's *Political Survey*, vol. ii. p. 205, note (D).

The distinguishing property of the blood-hound in chase, consists in his never changing from the scent on which he is first laid; and he will hunt by the shed blood of a wounded or dead animal as truly as he will by the foot, which rendered him so useful in pursuit of the deer or sheep-stealer.

The English stag-hound, now nearly gone, is little more than a mongrel blood-hound; at least it is reasonable to conclude, that the cross which produced him was directly from the English blood-hound with some lighter animal of a similar species (perhaps a greyhound, or lurcher) approximating his form, to which conjecture his figure and disposition, as well as his *comparative* inferiority of scent, appear to add strength. It is asserted in the *Sportsman's Cabinet*, that the stag-hound "was originally an improved cross between the old English deep-tongued southern hound and the fleeter fox-hound, grafted upon the basis of what was formerly called, and better known by the appellation of, blood-hound." But this assertion must have been made without proper reflection; for, in the first place, a cross between the deep-tongued southern and the fox-hound will not produce an animal nearly so large or so strong as the stag-hound; and, secondly, the stag-hound was known in England long before the fox-hound was made use of, or, indeed, before there was an animal at all resembling the one which is now known by that term.

We confess we regret the prospect of the total extinction of the English stag-hound, who, although his form possessed little of that symmetry we now see in the English fox-hound, was a majestic animal of his kind, and possessed the property peculiar alone to the blood-hound and himself, of unerringly tracing the scent he was laid upon, amongst a hundred others; which evinces a superiority, at all events a peculiarity, of nose entirely unknown to our lighter hounds of any breed. The want of being able to distinguish the hunted fox from a fresh-found one is the bane of English fox-hunting; and there are not wanting those who think, that in the breeding of the modern fox-hound, the minor points of high form and blood are more frequently considered than they should be, in preference of a regard to nose.

The Fox-Hound.

The English fox-hound of the present day is a perfect living model; but how he has become such, it is in no one's power to determine. Although we do not like to apply the term of mongrel to an animal we so highly respect, yet there can be no doubt of his being one of a spurious race, engrafted with care on the parent stock, namely, *the old English blood-hound.* There is, we believe also, no doubt that a century and a half ago there was no animal in the world resembling the present breed of fox-hound; and that the fox, when hunted at all in Great Britain, was hunted by a dog much resembling what is now known as the Welch harrier, rough-haired and strong, but of very far from sightly appearance. As all animals, however, improve under the care and guidance of man, until at length they assume the character of a distinct breed; such has evidently been the case with hounds, the breeders of which have, by going from better to better in their choice of the animals from which they have bred, progressively arrived at the perfection we see in them. And such has been the case with all our domestic animals, the breeders of which have alone attained their ends by the choice of individuals of the highest excellence in their kind, and by a judicious selection of size, form, and qualities likely to produce the result. There can be no doubt, then, but that by pursuing this course throughout a number of generations with the hound, an animal has been produced of what may be called quite a new variety in the canine race, answering the description and purposes of our present fox-hound. But the questions may be asked, Whence the necessity for this change, and forcing, as it were, nature from her usual course? Why not be content with the low-scenting, plodding hounds of our forefathers, which, from the superiority of their nose, not only displayed *hunting*, in the strict acceptation of that term, to the highest advantage, but very rarely missed the game they pursued? These questions are satisfactorily answered in a few words; first, as the fox is not now found by the drag, and the number of those animals is so greatly increased, the necessity for this extreme tenderness of nose does not exist; and, secondly, by reason of the blood of the race-horse having gradually mixed with that of our hunters, the sort of hound we have been alluding to was not found to be adapted to their increased speed; and particularly as, in proportion as nature lavished this fine sense of smelling on the old-fashioned hound, was he given to "hang" or dwell upon the scent, thereby rendering the length of a chase (which, to please the present taste, should, like Chatham's battle, be "sharp, short, and decisive") beyond the endurance of a modern sportsman. It is true, Mr Beckford, in his *Thoughts upon Hunting*, gives an instance of a pack of old-fashioned hounds, which ran in a string, as it were, one following the other, and yet killing twenty-nine foxes in twenty-nine successive runs, each fault being hit off by an old southern hound. But what would our hard-riding, modern sportsmen think of this as pastime? Nevertheless, all who witnessed, as we have done, the style of hunting of the Devonshire stag-hounds, will remember that there was a close similarity between them in chase, and the pack Mr Beckford speaks of. But, as the same eminent author afterwards observes, it is the dash of the fox-hound of the present day that distinguishes him from all others of his genus, and hounds must now "carry a head."

The breeding a pack of fox-hounds to a pitch bordering on perfection is a task of no ordinary difficulty; the best proof of which is to be found in the few sportsmen who have succeeded in it. Not only is every good quality to be regarded, and if possible obtained, but every fault or imperfection to be avoided; and although the good qualities of hounds are very soon reckoned, their faults in shape and performance present a longer catalogue. Independently of shape, which combines strength with beauty, the highest virtue in a fox-hound is not in the exquisiteness of his nose, but in his being true to the line his game has gone, and a stout runner to the end of a chase. But he must not only thus signalize himself in chase; he must also be a patient hunter, with a cold scent, or with the pack at fault. In short, to be a hard runner and a good hunter, and steady on the line, which "a good hunter" implies, constitutes a perfect hound, when combined with good form.

The faults of hounds, too often innate, can only be cured by education. The greatest of all are, skirting, or not being true on the line, and throwing the tongue improperly; first, without a scent, which is known by the term babbling; secondly, not throwing it at all, or running mute; and, thirdly, on a wrong scent, which is called running riot. The latter, however, is the least vice of the two, because generally curable by the lash; but the fault of skirting is too often innate; at all events, too often incurable. Thus has the breeder of the hound to guard against propensities as well as faults; and a late accredited writer on the subject says, "In modern times, the system of hunting is so much improved, so much more attention is paid to the condition of hounds and their style of work, that in this enlightened age a master of hounds thinks it a reflection on his judgment if *one* hound in his pack is detected in a fault."[1]

The selection of dog and bitch to breed from is a nice point for a master of hounds, or his huntsman, to decide upon; but, if he aim at excellence, he must keep his eye on perfection. In no animal is perfect symmetry so desirable as in a fox-hound, for without it there is no dependence on his services, however good may be his nature. We will first describe him in the words of a very old writer, and afterwards in those of Mr Beckford, when it will appear that there is a strong resemblance in the portraits drawn by each. "His head," says the former, "ought to be of middle proportion, rather long than round; his nostrils wide; his ears large; his back bowed; the fillets great; the haunches large; the thighs well trussed; the ham straight; the tail big near the reins, and the rest slender to the end; the leg big; the sole of the foot dry, and formed like a fox's, with the claws great." The latter says, "There are necessary points in the shape of a hound which ought always to be attended to; for if he be not a perfect symmetry, he will neither run fast nor bear much work; he has much to undergo, and should have strength proportioned to it. Let his legs be straight as arrows; his feet round, and not too large; his shoulders back; his breast rather wide than narrow; his chest deep; his back broad; his head small; his neck thin; his tail thick and brushy; if he carry it well so much the better." Now the hound that would answer to either of these descriptions would disgrace no man's kennel, and one resembling the latter would be an ornament to it; but with regard to the former, it must be borne in mind, that it is from the pen of a sportsman who wrote a century and half ago, when, as has been before observed, there is reason to believe no animal in the perfect form of the modern fox-hound was to be found in this or in any other country. Judges of the animal, however, will be disposed to think with us, that there is much of the real character of the *hound* in the sentence we have quoted from this old writer; such as the long rather than round head; the wide nostrils (Pliny says they should be flat, solid, and blunt); and the dry, fox's foot. But the "bowed back" appears to spoil all, unless by it is meant that gentle rise in the loins which the judge of hounds admires, and without which, the late Mr Chute of the Vine, in Hampshire, who hunted that country for more than thirty years, gave it as his opinion, no hound was able to maintain his speed for an hour over hilly and *ploughed* countries when "it carries;"—a technical term for the earth clinging to the foot, which it will do after a slight frost on the preceding night; necessarily adding much to the natural weight of the hound. Beckford gives us the modern fox-hound, and perfect, with the exception of the mention of one or two material points. "His chest should be deep," says he, "and his back broad;" but he has omitted a point much thought of by the modern sportsman, namely, *the back ribs*, which should also be deep, as in a strong-bodied horse, of which we say, when so formed, that he has a good "spur-place," a point highly esteemed in him. Nor is either of these writers sufficiently descriptive of the hinder legs of the hound; for although the "large haunch and well-trussed thigh" of the former denote power and muscle, nevertheless there is a length of thigh discernible in first-rate hounds, which, like the "well let-down hock" of the horse, gives them much superiority of speed, and is also a great security against laming themselves in leaping fences, which they are more apt to do when they become blown, and consequently weak. The fore legs "*straight as arrows*" is an admirable illustration of perfection in those parts, by Beckford; for, as in a bow, or bandy-legged man, nothing is so disfiguring to a hound as his having his elbows out, which is likewise a great check to speed. In some countries the round, cat-like foot is indispensable, and agreeable to the eye in all; but we would not reject a well-shapen puppy in other respects for somewhat of an open foot, provided his ancles or fetlocks were good, *a point we consider of the greatest consequence to all quadruped animals.* The shoulders of the fox-hound should resemble those of the horse—oblique, but at the same time strong; for a narrow chested hound is almost certain to get shaken by hard work, and consequently unlikely to endure beyond his third season.

As Beckford recommends the small head, we may presume the form and fashion of this point began to be changed in his time, and has, we think, been carried to too great an excess in the fox-hound of the present day, particularly in one or two kennels (the Belvoir, for example), where very short, as well as small heads, are a leading characteristic. For ourselves, we like some length of head in the fox-hound, not being able to divest ourselves of the idea of a cross with the pointer when we see him with a short head and a snubbed nose. Beckford also says the neck should be thin. We would add, *moderately thin.* We dislike a thin neck in any animal but the cow or the stag; at the same time we dislike a short, thick neck in a hound. His neck should be moderately long and moderately thick, with the muscles clearly developed; it should rise gracefully out of his shoulders, with a slight curve or crest, and, to completely satisfy the eye, should be quite free from exuberances of flesh and hair on the lower side of it, called by huntsmen "chitterlings" or ruffles, the hound having them being termed "throaty;" although there are numerous exceptions to this rule, as some of the best hounds England ever saw have been throaty; and although we are aware that one individual instance will prove neither the rule nor its exception, we can go as far back as to Mr Meynell's famous stallion hound Gusman, for as throaty, and yet as good a fox-hound as we ever remember to have seen. We agree with Beckford, that the "tail," now called stern, of a hound, should be "thick," and moderately "brushy;" and if well carried, it is a great ornament to a fox-hound. But there is one part of it which the master of a pack likes to see nearly deprived of its covering, and that is its tip, which, when in that state, is an infallible proof of a hound being a good, and not a slack, drawer of covers. As a perfect model we refer to the portrait of Nosegay, a hound belonging to the Earl of Kintore. Plate CCXCIV.

But to return to breeding the fox-hound. In the breeding of some animals, beauty of shape is often dependent on the caprice of fashion, or the taste of the breeder; but in the breeding of hounds no such latitude can be given, for here beauty, or symmetry of shape, is alone in reference to utility, and adaptation of parts to the purposes to which they are to be applied. Yet the breeder of fox-hounds has one point further to go; he must, as we before remarked, guard against *propensities*, which run in the blood of these animals perhaps stronger than their good qualities, and will sooner or later break out in their work. In the election then of a dog for a bitch, or a bitch for a dog, these matters must be attentively considered; and no man should breed from hounds of either sex that come under any of the following denominations, viz. not of a docile sort, but very difficult to enter to their game; given to run mute; to hang on a scent; or to be skirters; not only not true to the line, but given to run riot either in cover or in chase; and, above all things, if found evidently deficient in nose, and not able to run at head. Good constitution should likewise be looked to; but we would not reject a stallion hound, or a brood bitch, merely for being slack drawers, or for not being always at the head in chase, provided they were well bred, of good form, and true to the line, in cover, and out.

---

[1] Colonel Cook's *Observations on Fox-hunting*, &c.

As to the proper combination of form, that must be self-evident to the breeder of hounds. If a bitch is a little high on her leg, or light, she should be put to a short-legged, strong dog, and of course *vice versa;* if rather light in her tongue, that defect may be remedied by an opposite property in a dog. The defects in legs and feet can only be remedied by such means; and fortunate is it for the owner of an otherwise perfect and excellent bitch, that such remedies are at hand. Length and shortness of frame, as well as coarse points, are all to be obviated and altered in the same way, making allowance for the fact, that the laws of nature are not *always* certain. Constitution can likewise be mended by having recourse to that which is good (and none so easily detected as the dog's); and colour changed if required. In fact, as Beckford says, "It is the judicious cross that makes the complete pack;" and it was the remark of this practical writer, and therefore high authority amongst sportsmen, that "he saw no reason why the breeding of hounds may not improve till improvement can go no further." The question may be asked, is not his prediction verified?

But the act of crossing hounds, as indeed all other animals, although never thoroughly divested of chance, is one of more difficulty than most people would imagine, and one indeed which, by its results, would often baffle, if not puzzle, the profoundest of our modern physiologists. Our space will not admit of our going at length into this intricate subject, but great mistakes, we conceive, have been made by masters of fox-hounds, in breeding too much in-and-in, from nearest affinities, instead of having recourse to an alien cross. This was peculiarly apparent in the packs of two very celebrated masters of fox-hounds, the late Sir Thomas Mostyn, Bart., and the late John Corbet, Esq. of Sundorne Castle, Shropshire (the former of whom hunted Oxfordshire, and the latter Warwickshire, each for upwards of thirty years), who bred in-and-in, Sir Thomas from a bitch called *Lady*, and her produce; and Mr Corbet from a hound called *Trojan*, and his produce, to the great injury of their respective packs. We are aware it is asserted that a pack of fox-hounds should have the appearance and character of being of one family; but this expression is not to be taken in its literal construction. It is in the conformity of their character and appearance that they should bear a close resemblance to each other, and not in their close consanguinity. It is true, the celebrated pack of Mr Warde, the present father of the field, and a master of fox-hounds for the unparalleled period of fifty-seven years, which sold for two thousand guineas, only contained, in 1825, three couples of hounds not of his own blood, and those the produce of one stallion hound, Mr Assheton Smith's *Reubens*. But we have no proof of Mr Warde's hounds being better for adhering so closely to his own sort; on the contrary, it is the opinion, we believe, of the sporting world, reluctantly admitted, in consideration of the well-merited celebrity of their owner, that, latterly, the slackness of this renowned pack, unrivalled in fine form, was to be attributed to that circumstance. On the other hand, the rare but valuable combination of dash and nose, a match for the cold and ungenial Oxfordshire hills, for which the Duke of Beaufort's pack has been so long conspicuous, has been traced to his Grace's late huntsman, Philip Payne (said by Colonel Cook, in his *Observations on Fox-Hunting*, to be "the best judge of breeding hounds in the kingdom"), going from home for his blood, and sending his bitches to the celebrated stallion hounds of the best kennels within his reach. This, however, it must be remembered, is not within the command of every man's purse, the expenses attending sending bitches to a distance, under any circumstances, being heavy; as not only must they be placed under the care of a trusty servant on their journey, but there are other occult expenses attending them, which none but masters of hounds are aware of. It is, however, a notorious fact, that the produce of some stallion hounds, if they have a fair chance by the bitch, seldom fail in turning out well; and perhaps the most signal instance of "like begetting like" in this species of animal, is that of Mr Osbaldeston's Furrier having been the sire of an entire pack in that gentleman's kennel when he hunted the Quorndon country in Leicestershire, which he would occasionally take to the field, amounting to more than thirty-five couples, although, as may be supposed, they were generally mingled with the rest of his kennel, which at that period contained a hundred couples of hounds. These Furrier hounds gave little trouble in the entering of them, and proved very true line-hunters, and every thing that fox-hounds should be. The annals of fox-hunting likewise record similar instances of the peculiar properties of stallion hounds transmitting their virtues to many succeeding generations, especially in the instances of the Pychley Abelard, the Beaufort, and the New Forest Justice, Mr Ward's Senator, Mr Meynell's Gusman, Mr Musters's Collier, Mr Corbet's Trojan, Lord Yarborough's Ranter, with many others of more recent days, but too numerous to mention here.

The size, or, we should rather say, the height, of a fox-hound, is a point upon which there has been much difference of opinion. The long-established pack of the late Mr Chute were at least three inches below the standard of his neighbour Mr Villebois's large pack; also as much below that of his Grace the Duke of Cleveland, who had for many years also a large and a small pack; and at least four inches lower than Mr Warde's, in whose kennel were hounds full twenty-six inches high. Various arguments are made use of by the advocates of large and small hounds. Those of the former assert that they get better across a deep and strongly fenced country than smaller ones; whilst the admirers of the latter insist upon their being better climbers of hills, more active in cover, and quicker out of it when their fox is gone; and are oftener found to be perfect in form and shape. As to uniformity in size, how pleasing soever it may be to the eye, it is by no means essential to the well-doing of hounds in the field, and has been disregarded by some of our first sportsmen, the great Mr Meynell for one, who never drafted a good hound for being over or under size; neither did Mr Assheton Smith, when he succeeded to his, Mr Meynell's, country. The great object of both was to breed them with muscular power and bone, combined with as much symmetry as could be obtained; and to be equal in speed and good qualities, rather than equal in height.

We consider the proper standard of height in fox-hounds to be from twenty-one to twenty-two inches for bitches, and from twenty-three to twenty-four for dog hounds. The minimum and maximum size of the last fifty years would have been found in the kennels of Mr Chute and Mr Warde; the Duke of Cleveland and Mr Villebois coming next to Mr Warde in what may be called the maximum class. Mr Chute's motto over his kennel door was, "multum in parvo," which was his great aim; and although very full of power, and particularly neat in appearance, his hounds did not more than average twenty-one inches. On the other hand, many of Mr Warde's bitches, the most splendid animals of their kind and sex the world has ever yet seen, were better than twenty-three, and some of his dog hounds twenty-six inches high, which was about the standard of the original Devonshire stag-hounds. It may be said of hounds, however, as has been said of horses, that their height has little to do with their size, as far at least as their powers of action are concerned; and doubtless in all animals that labour, a medium height is the best.

The amount of hounds bred annually will depend on the strength of the kennel, and the number of days hunting in the week which the country they are intended for requires. From sixty to eighty couples are about the complement for a four-days-a-week country, which will require the breeding of a hundred couples of puppies every year, allowing the usual diminution of the entry by malconformation, under size, and that bane to the kennel, the distemper, which often takes off a moiety of them. As the period of gestation in the female dog is somewhat over two calendar months, the fox-hound bitch should, if she can be spared, be put to dog in January, as then she will litter in the spring, when the weather is comparatively mild (cold being destructive of young animals of this sort), and the puppies will then come early into kennel, generally be of good size, and powerful; and be entered without loss of time. The tips of their sterns being pinched off, and their dew-claws cut, whelps should be taken to their walks at about two months old; and if to one where there is plenty of milk or whey, they will be the better for it. Whelps walked at butchers' houses grow to a great size, but they are apt to be heavy-shouldered and throaty, and otherwise out of shape. If possible to avoid it, puppies should never be tied up, as perpetually drawing at the collar-chain throws their elbows out, and otherwise damages their legs, particularly by spreading their feet, and altering the form of their ancles, although it is sometimes almost impossible to avoid it, from their proneness to do mischief. If old bitches are bred from, they should be put to young dogs, and of course *vice versa;* and a bitch should not be worked for at least the last month of her time; and immediately on her whelps being taken from her, a dose of physic should be given her.

It is said that the dog in a state of nature is subject to few diseases, and for these he finds his cure by an instinctive faculty; in a domesticated state, however, he is subject to many, and some of an awful nature, which may be classed among the *opprobria medicorum*, no certain remedy being discovered for them. Amongst these is one called the distemper, not known by our forefathers, but at present become a sort of periodical disorder in kennels, to the destruction of thousands of young hounds annually. The first symptoms of this disease are, generally, a dry husky cough; want of appetite, and consequent loss of flesh; extreme dulness, and a running from the nose and eyes. As the disease advances, it is attended with twitchings of the head, while the animal becomes excessively weak in the loins and hinder extremities; is greatly emaciated; runs at the eyes and nose, and smells very offensively. At length the twitchings assume the appearance of convulsive fits, accompanied with giddiness, which cause the dog to turn round; he has a constant inclination to dung, with obstinate costiveness at one time, or incessant purging at another. Finally, the stomach becomes extremely irritable; every thing swallowed is instantly thrown up; and the dog generally dies in a spasmodic fit.

For the cure of this disorder many remedies have been prescribed; but as none of them can be relied upon as specific, we decline giving them,[1] and prefer transcribing the following observations of an intelligent and experienced huntsman in the service of a noble duke, accompanied by a comment upon it by a noble lord, also a practical sportsman, hunting his own fox-hounds.

" As soon," says the former, " as the young hounds come in from quarters, a sharp look-out is kept for the distemper; and as soon as any of its symptoms appear, a dose of cold-drawn castor oil is given, and the following morning a dose of calomel and jalap. About seven grains of the former and twenty of the latter made into a bolus, and put over their throats before they have tasted any thing, and their heads coupled up above the level of their bodies for two hours, so as to prevent them from vomiting up the medicine, which they are certain to do if this is not carefully attended to. They are then to have their broth and their meat. The oil and bolus to be repeated in a day or two as symptoms require; that is to say, if the fever runs high, repeat the bolus, and, if only to keep the bowels open, the oil in small quantities. Indeed the great thing is attending to circumstances, and acting accordingly; as, for instance, nothing can be more different than when flux attends the distemper, and when fits and obstinate costiveness is the case. I believe, however, that at first a good scouring in both cases is of service. In flux, of course, don't repeat the calomel, but take moderate means to stop it, as flux in a minor degree tends to keep off both fever and fits. To allay the flux, arrow-root, or boiled milk and flour porridge. There is no doubt that laudanum is the surest method to stop it, but then it is sure to end with fits. Fits at the beginning are no bad sign, and at the end nothing can be worse. I never either approved of bleeding or vomiting in the distemper; the first weakening too much, the latter creating and adding to the irritableness of their stomachs."

" With the foregoing plain, sensible, and simple treatment," says the noble lord in his comment on the foregoing observations, " my junior experience perfectly agrees with the opinion of ....; but I revert to what he justly adds about ' circumstances,' and differ with him about the bleeding, as I think a good scouring out, and bleeding, before any thing symptomatic of the disease has fairly begun, highly commendable. But, *vice versa*, for instance, if you bleed after the disease has fairly taken root, the lungs, nine cases in ten, being affected, it is ten to one you kill the dog; but if done early in the day, I cannot but think it is of much service, prevents fever, and in many cases makes the disease less violent. I think perhaps the treatment of whelps, after they come in from their healthy walks to the close confinement of sometimes an ill-kept kennel, is the cause of the distemper taking more violent hold of them than it otherwise would do; and amongst the hundred pretended receipts of many huntsmen, the remark is a justly correct one, of what *may* cure one dog will kill another. But here .... and his ' circumstances' put you right. What might be advisable would be this: As soon as your puppies come in, look them attentively over; divide the well-walked whelps from those that have been ill walked; bleed and scour well out the fat lot, paying of course attention to their diet, cleanliness, and exercise; and cherish the poor lot by the best food, giving them the castor oil without the calomel or the lancet. But a lot of well-bred fox-hound whelps are not to be left to the care of a whipper-in or a boiler, unless he is a perfectly sober, attentive, experienced man; for in this disease in the animal, as in the human species, the patient must be most attentively and closely watched."

---

[1] Colonel Cook says he has " sometimes" found the following efficacious:—Calomel three grains, cathartic ext. seven ditto, soap seven ditto, emetic tartar one half grain. Make three pills, and give one every other day. Vaccination was tried in some kennels as a preventive, but it failed, and was abandoned.

Kennel Management.

The management of hounds in kennel has undergone great changes for the better since Mr Beckford's day; and, divesting the mind of the inferiority of horse flesh over cow or bullock flesh, the food of hounds, both in its nature and the cooking of it, is such as man might not only not reject, if necessity compelled him to have recourse to it, but such as he would thrive and do well upon. It is a common expression, that "any thing will do for dogs," and experience informs us they will exist upon very miserable fare; but hounds, *to be in condition*, must have every thing good of its kind, and also well cooked. Were a master of hounds, or huntsman, of the present day, to follow Beckford's advice, of putting his hounds to a horse fresh killed, after a hard day, his brother sportsmen would think him mad; nor is there scarcely any thing now used in our first-rate kennels but the best oatmeal (Scotch or Irish is the best), one year old, and well-boiled horse flesh, quite free from taint. The meal is put into the copper when the water boils, and should be boiled up a second time, and, in all, for at least two hours; for nothing is worse for the wind of hounds than meal not thoroughly boiled. When taken out of the boiler, it forms a substance resembling coarse rice pudding; and when the fresh flesh, which is shredded, and the broth in which it is boiled, are added to it in the trough, and very well mixed, it forms the best and highest food that can be given to hounds. In some kennels, after the example of that famous huntsman the late Thomas Oldacre, the meal and flesh are boiled up together, with the idea that more of the virtue of the flesh is then imparted to the meal than when it is merely mixed with the broth; but the practice is not general. But such is the difference of constitution in hounds, and the aptitude of some, over others, to gain flesh, or become foul, persons who are particular as to the condition of their pack have troughs filled accordingly, that is, one with thinner food than another, for hounds of the former description. No animal in the world is so soon up and down in his condition as the dog; and, strange as it may appear, the effect of two or three extra mouthfuls of thick meat will be visible on some hounds on the second day after they have eaten them. Nevertheless, the dog being strictly a carnivorous animal, cannot stand hard work without flesh, which he should have a fair allowance of once a day, according as his constitution may require it. Some masters of hounds, however (the justly celebrated Mr Ralph Lambton one of them), do not feed with flesh on the day before hunting, giving only meal and broth; and this on the supposition that the faculty of scent is more delicately susceptible without it. Young hounds lately come from walks should be fed twice in the day, as they do not always, at first, take to kennel food.

Colonel Cook is thus explicit and correct on the subject of feeding hounds, and their condition, the result of many years experience, and great attention to the kennel. "It is quite certain," says he, "a hound too high in condition cannot run a burst, neither can a poor half-starved one kill an afternoon fox; a hound, therefore, cannot be considered as fit to be brought out, if he is either too high or too low. I like to see their ribs, but their loins should be well filled up, and they should be hollow in their flanks: he that is full in the flanks is sure to be fat in the inside, and consequently not fit for work. The feeding of hounds, and the bringing them to cover, able to run a burst, or kill an afternoon fox, is not altogether a thing so easy as some people imagine; in fact, it requires nearly as much trouble to get a hound into condition as it does a horse; and if the greatest attention is not paid to this particular, you cannot expect to catch many foxes. It is the condition of a hound which gives him the advantage over the animal he hunts. Nevertheless their constitutions differ as much as those of the human species; some require thick food, others thin; the same quantity which may be requisite for Ranter, if given to Rallywood, would render him unable to run a yard. Some time before hunting (say about three weeks), they should have plenty of walking exercise, and salts given them once a week. If a hound is at any time very foul, the following receipt is very efficacious:—Three grains of Æthiops mineral, five grains of calomel, made into a ball: the hound must of course be carefully kept from cold water."

In the summer time, when hounds are out of work, they do not require flesh more than twice a week, and succulent vegetables in their food are at this time useful. They are also physicked and bled at the close of one season, and before the commencement of the next; and, if necessary, dressed over with a sulphureous mixture during the idle months. But some owners of hounds, and huntsmen, object to dressing them, conceiving that it opens their pores too much, and subjects them to rheumatic affections.

One recent and great improvement in kennel discipline is, a small reservoir of water within the walls, of sufficient depth to cleanse the legs of hounds, but not to wet their bodies, which they are made to walk through immediately on their coming home. Upon being turned into their lodging room, they commence licking themselves dry, which, as a dog's tongue is proverbially called his "doctor," is most beneficial to their feet, by clearing them of sand or gravel, as well as healing any trifling wounds which they may have received. In the Duke of Cleveland's kennel, this reservoir is filled with broth, which, in addition to its healing properties, induces hounds to lick their feet still more than water does. In flinty countries, the feet of hounds are very frequently wounded, which is a great disadvantage to those a little inclined to do wrong, as they are compelled to miss their turn, and so get above themselves. It also obliges a gentleman to keep a larger number of hounds than this country would otherwise require.

Hounds are fed on the day before hunting about eleven o'clock A. M., but some delicate feeders require to be let into the troughs a second time. After hunting, they are fed as soon as they have licked themselves dry, which, by the warmth that arises from their bodies when shut up, is very soon effected; and in the summer time it is reckoned safer to feed them in the evening, as they then rest quieter throughout the night, and are less disposed to quarrel.

Colour of Hounds.

Independently of the justness and elegance of figure in animals, which adapt them to the uses or ends of their creation, nature has been profuse in the adornment of the surface of their bodies by various beautiful colours. But in proof that the Creator never errs from his design in any of the qualities he has communicated to his creatures, and that he adorns not merely for the sake of ornament alone, these beauties conferred upon them are found greatly to contribute to their well-being; for with them they have received the consciousness of possessing, and a desire to preserve them. In fact, it is this which attaches them so closely to their being, and renders them so attentive to cleanse, ornament, and take care of themselves, as we every day see they do; and to preserve, in all its lustre, the enamel which nature has given them. And we may go even one step farther than this. An accurate observer of animals will perceive, that they are not only conscious of their own beauty, but are capable of beholding and admiring it in others. This is undoubtedly the case with regard to both sexes of the same species: never are they so attentive to display the graces which nature has bestowed upon them, never are they so ostentatious, as when they are together, which is evident from their gambols and frolics; and, if we may judge of them from our own feelings, how greatly must this disposition contribute to their mutual felicity.

In no animal is variety of colours more conspicuous than in hounds, and it adds greatly to their appearance when we see them in a body in the kennel, but still more so in the field. The prevailing ones with the fox-hound are these: Tan (not common); black (not common); black and white and tan (the most common); milk white (not common); red (very rare); blue (the same). Next come the blended, or mixed colours, known in the kennel as "pies." There is the red pie; the blue pie; the yellow pie; the grey pie; the lemon pie (very handsome); the hare pie; and the badger pie, which last is very characteristic of the fox-hound. The fox-hound is sometimes ticked, that is, his coat is dotted with small white specks on a dark ground, but he is rarely what is called "mottled" (motley); and, we believe, what is known by "a blue mottled hound" is not to be found among fox-hounds, being peculiar to harriers and beagles. There was for many years a pack of "blue mottled" harriers kept near Croydon, in Surrey.

It is asserted that the original colour of the English fox-hound was fallow, or pale yellow (Shakspeare speaks of a fallow *greyhound*); and we are inclined to this opinion from its being spoken of in several old works upon hunting, as the "best colour for hounds that hunt the hart or roe;" and there can be no doubt of our fox-hounds being originally descended from that breed of dog, be it what it may. As we know that a recurrence to original colour frequently takes place in animals and birds, after its disappearance throughout several generations, this may probably account for the various pied hounds we see in kennels, the produce of hounds of distinct colours, perhaps merely black and white, and often of those nearly black. Moreover, at Ashdown Park, in Berkshire, an old seat of the Craven family, there is a picture of a pack of fox-hounds, above a hundred years old, in which every hound is either fallow coloured or red.

The Tongue, or Cry of Hounds.

During the early stages of mental progress, the ear is of more importance to man than the eye. Indeed at all times sounds, by association, become the signs of ideas; and the great variety in the voice of nature must have been designed to meet the peculiar tastes and purposes of the countless multitudes that dwell on the face of the earth. That the cry of hounds is a voluntary noise, proceeding from a powerful organic impulse, is quite apparent, as is also the purpose for which the impulse is given; namely, to announce their having discovered the scent of an animal, either obnoxious to their notice, or desirable as food, and by calling their straggling companions together, and uniting their forces, the better to enable them to secure their prey. On the other hand, here is mercy shown to the prey they are in pursuit of. The tongue of the hound gives notice of his approach; and he does not pounce upon his victim as the silent greyhound does, which Gratius, in his poem on coursing, alludes to in the following verse:—

> "Sic canis illa suos taciturna supervenit hostes."

But the cry of hounds, melodious and heart-cheering as it even now is, has lost much of its poetical interest, from the change man has made in the natural organization of the animal from which it proceeds; and we shall never again hear of a master of a pack, after the manner of Addison's knight, returning a hound that had been given to him as an "excellent bass," whereas the note he wanted was a "counter-tenor." The great Beckford, however, was something of the worthy knight's opinion; for he says, in his *Thoughts upon Hunting*, "If we attended more to the variety of the notes frequently to be met with in the tongues of hounds, it might greatly add to the harmony of the pack." This is well in theory. The natural organization of the dog is musical; he is, in fact, a victim to musical sensibility; and we may reasonably suppose that the notes of his companions in the chase may be as pleasing to himself as to his huntsman; but we more than doubt whether a huntsman of this day would draft a highly-bred and beautiful young bitch, as good too as she looks to be, merely because her light, fox-hunting tongue might be somewhat drowned, and now and then lost, in the general chorus of the pack. He would rather say, "*Let every tongue be a fox*,[1] and I'll leave the rest to chance." But, on a good day for hearing it, what *natural* sound is more delightful and animating than that of hounds in full cry, in the deep recesses of an echo-giving wood? Neither would those writers who have availed themselves of the beauty and sublimity which allusions to sounds in nature stamp on their various compositions, have at all descended from their eminence if they had, like Shakspeare, delighted as much in bringing the soul in contact with such a sound as this, as with the rolling of the thunder, or the howling of the storm.

The Age of Hounds.

The dog exhibits no exact criteria of age after the first two years, during which time the whiteness and evenness of his teeth are a pretty certain test of his not exceeding that period. An old hound, however, cannot be mistaken if only looked in the face, where he shows old age nearly as distinctly as man. As to the length of services of hounds, that depends upon circumstances. Few are found in a kennel after their eighth year, and *very few* after their ninth; and not many hard-working hounds can "run up," or keep pace with the rest, after their fifth season at most. Hounds are in their prime in the third and fourth years; and although there are a few instances, such as Sir Richard Sulton's Lucifer, the Beaufort Nector, and the Cheshire Villager, of their hunting in their twelfth, eleventh, and tenth year, the average of their work cannot, we fear, be placed beyond four seasons. Old hounds are useful in the field, but when they cannot run up with the pack, they should be drafted. The perfection of a pack consists in the great body of it being composed of hounds *quite in their prime.*

Separation of the Sexes.

The separation of the sexes in the kennel *and in the field* is one of the late innovations in the sporting world, and generally considered as a good one. In the first place, it pleases the eye to see a pack of hounds nearly all of a size, which cannot be the case when it is composed of dogs and bitches mixed; and the character of the animal is likewise more uniformly displayed when confined to one individual sex. Secondly, by the total separation of dogs and bitches in the kennel and in the field, the former are less inclined to quarrel, and the latter are more at their ease, than when subject to the constant, and, at times, importunate solicitations, of the male sex. Of their performances in the field, however, when taken into it separately, some difference of opinion exists; and each sex has its advocates. With a good fox before them, and a warm scent, bitches are decidedly quicker, and more off hand in their work, than dog hounds; but with a colder scent, or at fault, the general opinion is, that they are not so patient, and more given to over-run it. That they are superior in "*dash*," which, Beckford says, is the distinctive characteristic of a fox-hound, we believe is universally acknowledged; and a celebrated master of hounds,[1] who hunted them himself several seasons in Leicestershire, has been heard frequently to say, that if his kennel would have afforded it, he would never have taken a dog hound into the field. That, in the canine race, the female has more of elegance and symmetry of form, consequently more of speed, than the male, is evident to a common observer; but there is nothing to lead us to the conclusion, that, in the natural endowment of the senses, any superiority exists. It is however remarkable, that the Latins, when speaking of hunting, or "sporting dogs," as we call them, generally use the feminine gender, one instance of which is to be found in the second ode of the fifth book of Horace (*multa cane*), which ode every sportsman ought to read, as it gives so pleasing a picture of a country life.

---

[1] "Every tongue a fox," is a well-known sporting phrase.

Names.

The naming of hounds and horses has nearly exhausted human invention, as well as classical research. Beckford furnishes a list of more than eight hundred names for hounds, alphabetically arranged. But the naming of hounds is somewhat under metrical control; for it is not only confined to words of two and three syllables, but their quantity, or rather their time, must be consulted. For example, a dactyl, as *Lucifer*, answers well for the latter; but who could holloa to *Aurora?* a trochee, or an iambus, is necessary for the former, the spondee dwelling too long on the tongue to be applied smartly to a hound. But there ought to be a nomenclator, as of old, at every kennel door; for it is but few persons unconnected with a pack that can recollect their names until after a rather long acquaintance with them, from the great similarity of form, character, as well as sometimes of colour, in old-established kennels. "How is it possible," said a young master of fox-hounds a few years ago, "that I should distinguish every hound in my kennel by his name, when I find *three* spots on one side of their body, and *five* perhaps on the other?" There have been, however, and still are, persons who can see a large kennel of hounds *once* drawn to their feeding troughs, and call them all by their names afterwards, the result alone of a keen and practised eye.

The price of hounds is strangely altered within the space of half a century, or less; and on this subject we cannot do better than quote Colonel Cook. "Hounds," says he (p. 6), "have always been much undervalued; we sometimes hear of eight hundred or even a thousand guineas as the price of a hunter, and the sum of three or four hundred is often considered as a mere trifle; whereas a pack of hounds, *on which every thing depends*, was only considered worth a few hundreds. Yet Shakspeare himself appears to have known the value of a hound; for in his "Induction" to the *Taming of the Shrew*, a nobleman returned from hunting thus speaks of his hounds with delight to his huntsman:

> *Nobleman.* Huntsman, I charge thee, tender well my hounds;
> Brach Merriman,—the poor cur is emboss'd,
> And couple Clowder with the deep-mouth'd brach.
> Saw'st thou not, boy, how Silver made it good,
> At the hedge-corner, in the coldest fault?
> I would not lose the dog for *twenty pound.*
> *Huntsman.* Why, Belman is as good as he, my lord;
> He cried upon it at the meerest loss,
> And twice to-day pick'd out the dullest scent;
> Trust me, I take him for the better dog.

"The sum of twenty pounds for a single hound in Shakspeare's time," continues the colonel, "and that not the best in the pack either, was no inconsiderable price. I am not alluding to 'a lot of curs;' but surely a well-bred, established pack of fox-hounds, including brood bitches, and puppies at walk, must be cheap at a thousand or twelve hundred pounds."

Now the value of anything is what it will fetch; and how far an established pack of fox-hounds is cheap at a thousand or twelve hundred pounds, is a matter of consideration with reference to concomitant circumstances; but that they will have cost the seller a great deal more, there can be no doubt. We should put the average price at something less than either of the above sums, although, within the last dozen years, several packs have been sold for the former sum; and the justly renowned one of Mr Warde, the present Father of the Field, fetched two thousand guineas; and the late Lord Middleton gave Mr Osbaldeston the same sum for ten couples of hounds out of his kennel.

The Harrier.

The modern harrier bears no greater resemblance to the one in use fifty years back, than the hunter of the present day to that ridden by our grandfathers. In fact, he is now nothing less than the fox-hound in miniature, which it is the endeavour of all breeders to have him. Their qualities also are as opposite as their form, the one delighting to dwell upon the scent, the other a little inclined, perhaps, to the other extreme. But the taste of the day for all sports of the field would not endure the tedious exactness of the old psalm-singing harrier; and not only in point of diversion, but on the score of the *pot*, the balance is greatly in favour of the improved variety. Before the old-fashioned harrier, the hare had time to play all sorts of tricks, to double on her foil, and so stain the ground that she often escaped by such means; whereas the modern hound, if the scent be tolerably good, forces her from her foil to fly the country, and very often beyond her knowledge, when a good straightforward run is the almost invariable result. The observation of Mr Beckford holds good here. He could not, he said, imagine a hound too *well* bred to show sport, and kill his game; but he could readily conceive the reverse, when the game ran stout and well.

To Sir John Dashwood King, Bart. of West Wycombe Park, Bucks, is the credit due for what may be termed the living model of the present improved harrier; and so characteristically stamped are his sort of hound, now widely spread, that they are recognised by a sportsman at the first glance. Their standard height did not exceed eighteen inches, and therefore, in that respect, they were not an overmatch for their game; but from the great equality of their size and speed, combined with rare hunting qualities, they killed more hares, with good runs, than any other pack in the kingdom, and for many, many years in succession certainly "bore the bell." Sir John kept them more than thirty years, at Bourton-on-the-Hill, Gloucestershire, near the four-shire stone on the Oxford and Worcester road, where his father kept them before him; hunting partly in the vales of Warwickshire and Worcestershire, and partly over the Cotswold Hills, which latter country is famous for the stoutness of its hares, frequently standing an hour before this celebrated pack, after having been driven beyond their knowledge by their *pressing* method of hunting up to them, a method quite unpractised by the old long-eared harrier. The parent stock of this pack was a small fox-hound from the Duke of Grafton's kennel, called Tyrant, whose blood, form, and character, were strikingly apparent throughout; and so great was its celebrity, that it fetched the highest price ever known to be given for harriers, namely, seven hundred guineas, by Lord Soudes of Rockingham Castle, Northamptonshire. Sir John, however, deserved success. He bred upwards of seventy couples of hounds every year, and had an establishment of horses, &c. nearly equal to fox-hounds. The hare-hounds bred for many years by Mr Yeatman of Stock House, Dorsetshire (who lately resigned the Blackmore vale country, in which he hunted foxes), came next to Sir John's in the true form and character of the modern harrier.

---

[1] Sir Bellingham Graham, Bart. of Norton Conyers, Yorkshire.

The Stag-Hound.

The English stag-hound is now known only by name, as there are none of the breed kept for the purpose of hunting the wild stag; and such deer as are turned out before his majesty's, and the few other packs that follow this game, are hunted by fox-hounds of the highest blood that can be procured. And the change is a good one; for although the English stag-hound was a noble animal of his kind, he was not sufficiently speedy, nor perfect in his work, to satisfy the present taste, and he was likewise too much given to dwell on the scent in chase, as well as of very delicate constitution in kennel. He is originally supposed to be the produce of the old English blood-hound, by a cross of some kind of greyhound, such as the Highland deer-greyhound, approximating his own form. At all events, it is certain that the former, the blood-hound, was the dog first made use of in hunting deer in England; and it is probable that, as the taste for following hounds on horseback increased, a turn of speed was given to the original breed by a cross with a speedier sort. We may add, the old paintings of English stag-hunting favour this hypothesis.

The Beagle.

This variety of the dog is now nearly extinct, and for the same cause as the stag-hound. Time is at present considered as too precious to afford an hour at least, and perhaps two, to the hunting down one hare, which is now accomplished in a more off-hand manner, in twenty minutes. To an admirer of nature, however, and of the endowments given to inferior animals, the busy, intelligent, and highly-gifted beagle certainly affords a treat. His form, also, when not out at his elbows, is handsome in the extreme, and his perseverance in chase is exceeded by none. But he has one of the greatest faults that hounds can possess; he is noisy, and dwells upon the scent, whilst his game is flying the country before him. In fact, his only use or value now is (independently of being looked at and admired, for he is a perfect animal of his kind), to accompany a brace of greyhounds when a hare is wanted, and not ready at hand. There is, however, one pack of beagles kept in Dorsetshire, known as the Mountain Harriers, whose performances are much spoken of in the sporting world.

The Greyhound.

The greyhound has now lost his place in the catalogue of the dogs used in chase, neither can be classed as such, since man has deprived him of the necessary faculty of smell; but he was held in such high estimation in the middle ages, as to be considered as the peculiar companion of a gentleman. He never went abroad without these dogs; the hawk which he bore upon his fist, and the greyhounds which ran before him, were certain testimonies of his rank; and in the ancient pipe rolls, payments appear to have been often made in these valuable animals. But at no period of his existence was the greyhound the symmetrically elegant animal we now see him, nor possessed of nearly so much speed; neither was the diversion of the leash at any time carried on with so much spirit as within the space of the last thirty years, in various parts of Great Britain. But the necessity for, or rather the cause of, the change in the form of the greyhound, may be traced to his being no longer, as formerly, made use of to course and pull down deer, but chiefly to exhibit his speed at our different spirited coursing meetings, for the various prizes contended for, as also in private matches.

The *Courser's Manual or Stud Book*, by Thomas Goodlake, Esq. (1828), has the following interesting passages on the alteration effected in this species of dog. "In the days of Elizabeth," says the author, "the greyhound seems to have been a fine and effective animal, but approaching more to the bony, wire-haired make of the Highland greyhound represented in the pictures of Edwin Landseer, and deficient in the symmetry and fine glossy coat which mark a high-bred kennel of modern times. It is probable, that during the early part of the seventeenth century, judicious crosses were made, partly from the beautiful Italian greyhounds, which we often see in family pictures, accompanying our fair ancestresses in their parks and plaisances, and partly from the stouter breed of dogs represented in Flemish hunting-pieces; and that even Persia and Arabia, whose greyhounds are not to be despised in point of form and speed, contributed their quota of blood; as it is shown by the history of Cromwell's Coffin Nail, that the wealthier gentry of that period spared no expense or pains in improving the more highly-prized breeds of sporting animals. If we mistake not, some of the pictures of Charles the First contain portraits of greyhounds approaching nearly in point of coat and shape to the present breed."

Speaking of the late Lord Orford, who, with respect to modern coursing, laid the foundation-stone of the celebrity to which it has arrived, and who, besides being celebrated for his greyhounds, established the first coursing club that we read of, at Swaffham in Norfolk, in the year 1776, the same writer says, "A few anecdotes of this noble patron of coursing may not be uninteresting. He was passionately fond of the sport; and as he was a man who never would do things by halves, but was zealous beyond measure in succeeding in whatever he undertook, he may be said to have made as much progress as possible in perfecting the breed of the greyhound, and encouraging an emulative spirit in coursing amongst his opulent neighbours, from the time he took it up till his death. Indeed, his extensive property, and his influence as lord-lieutenant of Norfolk, gave him the greatest means of accomplishing his favourite object. He could command such an immensity of private quarters, or walks as they are generally called, for greyhounds, that he bred largely, and few possessed the same advantages of selection. He is recorded as having at one time fifty brace of greyhounds; and it was his fixed rule never to part with a single whelp till he had had a fair trial of his speed; consequently he had chances beyond almost any other individual, of having a collection of very superior dogs. Intent on obtaining as much perfection in the breed as possible, he introduced every experimental cross, from the English lurcher to the Italian greyhound. He it was that first thought of the cross with the English bull-dog, in which he persevered in opposition to every opinion, until, after breeding on for seven removes, he found himself in possession of the best greyhounds at the time ever known; and he considered that this cross produced the small ear, the rat-tail, the fine, thin, silky coat, together with that quiet, innate courage which the high-bred greyhound should possess, preferring death to relinquishing the chase." There is something curiously analogous in the sense conveyed by the concluding words of this extract. His lordship fell dead from his horse immediately after witnessing the triumph of his famous bitch Czarina, in a match at Swaffham, having been in vain admonished on the impropriety of taking the field in his then indifferent state of health; and his memory is introduced as a toast at most coursing meetings, as father and patron of the sport.

The Terrier.

The terrier is no longer the accompaniment to a pack of fox-hounds, and for the best of all reasons,—foxes are not nearly so often digged for as formerly; and his only use was, by his bay, to inform the diggers whereabouts the fox lay; and we suppose he took his name from his being so eager to get under ground. There is also a second reason why he is better left at home. He was seldom steady from *wing*, if he was from *foot*, and thus often the cause of riot. It was, however, a matter of astonishment to behold those which were very highly bred, making their way, as they did, to the end of the longest chases, over strong and wet countries, as well as through the thickest covers, and so often making their appearance at the end of them. At all events, if left behind, they were sure to find their way home in the course of the night, whatever the distance might be. One peculiarity of form was essential to their being sure of getting up to their fox, viz. not too full in the shoulder; and those whose colour was pure white, and who were broken-haired, were generally most esteemed by huntsmen. It was often their lot to lose their life, by scratching up the earth behind them, and cutting off their means of retreat; and they were now and then killed by a fox, the latter a rare occurrence. They were commonly entered to a badger, whose bite is more dangerous than that of a fox. (B. B. B. B.)

HOUNSLOW, a town, part of the parish of Heston, in the hundred of Ossulton and county of Middlesex, ten miles from London. It is on the great western road, and more post-horses are kept there than at any other town in England. Near to it are some considerable powder-mills, and also mills for rolling copper. On what was formerly Hounslow Heath, but now enclosed, there are extensive barracks for cavalry.

HOUR, in *Chronology*, an aliquot part of a natural day, usually a twenty-fourth, but sometimes a twelfth. Originally the word *hora*, or ὡϱα, comes, according to some authors, from a surname of the sun, the father of hours, whom the Egyptians called *Horus*. But others derive it from the Greek ὁϱιζειν, *to terminate*, or *distinguish*; and others again from the word ὑϱον, *urine*, conceiving that Trismegistus was the first who settled the division of hours, from observing an animal consecrated to Serapis, named *cynocephalus*, which made water twelve times a day, and as often in the night, at equal intervals.

An hour with us is a measure or quantity of time, equal to a twenty-fourth part of the natural day, or nycthemeron; or the duration of the twenty-fourth part of the earth's diurnal rotation. Fifteen degrees of the equator answer to an hour, though not precisely, but near enough for common use. The hour is divided into sixty minutes, the minute into sixty seconds, and so on. The most ancient hour is that of the twelfth part of the day. Herodotus, (lib. ii.) observes that the Greeks learned from the Egyptians, amongst other things, the method of dividing the day into twelve parts. The division of the day into twenty-four hours was not known to the Romans before the first Punic war. Until that time they only regulated their days by the rising and setting of the sun. They divided the twelve hours of their day into four, namely, *prime*, which commenced at six o'clock; *third*, at nine; *sixth*, at twelve; and *none*, at three. They also divided the night into four watches, each containing three hours.

HOURS, HORÆ, in the ancient mythology, were certain goddesses, the daughters of Jupiter and Themis. At first they were only three in number, Eunomia, Dice, and Irene; but to these were afterwards added two more, Carpo and Thallote. Homer makes them the doorkeepers of heaven, and Ovid allots them the employment of harnessing the horses of the sun.

HOURS, *Horæ*, in the Roman Catholic church, are certain prayers performed at stated times of the day, as matins, vespers, lauds, and the like. The lesser hours are, *prime*, *tierce*, *sixth*, and *none*, and they are called *canonical hours*, as being prescribed by the canons of the church in commemoration of the mysteries accomplished at those hours. These hours were anciently called *course*, *cursus*; and Mabillon has written a dissertation on them, entitled *De Cursu Gallicano*. The first constitution enjoining the observation of the canonical hours is dated in the ninth century; being found in a capitular of Heito, bishop of Basil, directed to his curates, importing that the priests shall never be absent at the canonical hours either by day or by night.

HOUR-Glass, a popular kind of chronometer or clepsydra, serving to measure the flux of time by the descent or running of sand out of one glass vessel into another.

HOURIS, in modern history, is a name given by the Mahommedans to those females who are designed for the faithful in Paradise. These are not the same as those with whom they had lived on earth, but are formed for this purpose with singular beauty and undecaying charms. Islamism is not more distinguished from Christianity by its inherent character than by the rewards which it holds out to its faithful votaries. The latter is the religion of a civilised people, and is entirely spiritual: the reward which Jesus promises to the elect is that they shall see God face to face. In the Christian religion, therefore, every thing tends to mortify the senses, nothing to excite them. Islamism, on the contrary, is the religion of a people in the infancy of civilisation; it arose in a poor country, destitute of the necessaries of life, amongst a people fierce and warlike, who were incapable of being addressed through the medium of their understandings. Mahommed therefore appealed to the senses. He promised his followers odoriferous baths, rivers of milk, fair black-eyed houris, and groves of perpetual shade. The Arab, thirsting for water, and parched by a burning sun, sighed for shade and coolness, and was ready to do any thing for such a recompense. The religion of Mahommed may consequently be said to be a religion of promise; it appeals to the senses, it addresses the passions, it holds out the prospect of revelling in those pleasures which are most desired and pursued by men in whom the merely sensual predominates over the intellectual part of their nature. But Christianity, which sprung from a purer source, considered the rewards of a future life as insufficient to repress the vices, disorders, and crimes, which spring from the passions, and, superadding to its precepts a penal sanction, may justly be said to be a religion of menace. From these general principles may be deduced the opposite characters of the two religions; the one appealing only to the senses and the passions; the other addressing itself to the minds and consciences of mankind, and having for its grand object to reform, not to debase society.

HOUSE, a habitation, or place built with conveniences for dwelling in. See Architecture and Building.

Houses, amongst the Jews, Greeks, and Romans, were flat-roofed, and had usually stairs on the outside, by which they might ascend and descend without coming into the house. Each house, in fact, was so laid out that it enclosed a quadrangular area or court. This court was exposed to the weather, and being open to the sky, gave light to the house. This was the place where company was received, and for that purpose it was strewed with mats or carpets for their better accommodation. It was paved with marble or other materials, according to the owner's ability, and provided with an umbrella of vellum to shelter them from the heat and inclemency of the weather. This part of their houses, called by the Romans *impluvium*, or *cava ædium*, was provided with channels to carry off the water into the common sewers. The top of the house was level, and covered with a strong plaster by way of terrace. Hither, especially amongst the Jews, it was customary to retire for meditation, private conversation, devotion, or the enjoyment of the evening breezes.

The Grecian houses were usually divided into two parts, in which the men and women had distinct mansions assigned. The part assigned to the men was towards the gate, and called ανδρωνιτις; the apartment of the women was the farthest part of the house, and called γυναικωνιτις. Jews, Greeks, and Romans supposed their houses to be polluted by dead bodies, and to stand in need of purification.

House, in *Astrology*, denotes the twelfth part of the heavens. The division of the heavens into houses is founded upon the pretended influence of the stars, when meeting in them, upon all sublunary bodies. These influences are supposed to be good or bad; and to each of these houses particular virtues are assigned, on which astrologers prepare and form a judgment of their horoscopes. The horizon and meridian are two circles of the celestial houses, which divide the heavens into four equal parts, each containing three houses, six of which are above the horizon, and six below it; of these, six are called *eastern* and six *western houses*.

A scheme or figure of the heavens is composed of twelve triangles, all called *houses*, in which are marked the stars, signs, and planets, so included in each of these circles. Every planet has likewise two particular houses, in which it is pretended that they exert their influence in the strongest manner; but the sun and moon have only one, the house of the former being Leo, and that of the latter Cancer.

The houses in astrology have also names given them according to their qualities. The first is the house of life, which is the ascendant, extending five degrees above the horizon, and the rest below it. The second is the house of riches; the third, the house of brothers; the fourth, in the lowest part of the heavens, is the house of relations, and the angle of the earth; the fifth, the house of children; the sixth, the house of health; the seventh, the house of marriage, and the angle of the west; the eighth, the house of death; the ninth, the house of piety; the tenth, the house of offices; the eleventh, the house of friends; and the twelfth, the house of enemies.

HOUSEHOLD, the whole of a family considered collectively, including the mistress, children, and servants. But the household of a sovereign prince includes only the officers and domestics belonging to his palace.

The principal officers of the household of the king of Great Britain are, the lord steward, the lord chamberlain of the household, the groom of the stole, the master of the great wardrobe, and the master of the horse.

The civil government of the king's house is under the care of the lord steward of the king's household, who, being the chief officer, is entitled to have all his commands observed and obeyed. His authority extends over all the other officers and servants, excepting those of his majesty's chapel, chamber, and stable; and he is the judge of all crimes committed either within the court or the verge.

Under him are the treasurer of the household, the comptroller, cofferer, the master of the household, the clerks of the green-cloth, and the officers and servants belonging to the accounting-house, the marshalsea, the verge, the king's kitchen, the household kitchen, the acatery, bakehouse, pantry, buttery, cellar, pastry, &c. Next to the lord steward is the lord chamberlain of the household, who has under him the vice-chamberlain, the treasurer, the comptroller of the chamber; forty-eight gentlemen of the privy chamber, twelve of whom wait quarterly, and two of them lie every night in the privy chamber; the pages of the presence-chamber; the mace-bearers, cup-bearers, carvers, musicians, and others.

The groom of the stole has under him the eleven other lords of the bed-chamber, who wait weekly in the bedchamber, and also the grooms of the bed-chamber, the pages of the bed-chamber, and back stairs, &c.

The master or keeper of the great wardrobe has under him a deputy, comptroller, clerk of the robes, brusher, &c. and a number of tradesmen and artificers, who are all sworn servants to the king.

The master of the horse has under his command the equerries, pages, footmen, grooms, coachmen, farriers, saddlers, and all the other officers and tradesmen employed in his majesty's stables.

Housing, or *House-Line*, in nautical language, a small line formed of three fine strands or twists of hemp, smaller than rope-yarn. It is chiefly used to seize blocks into their strops, to bind the corners of the sails, or to fasten the bottom of a sail to its bolt-rope, and the like.

Housing, or *Housee*, a cover laid over the saddle of a horse, in order to save it from the weather, dirt, and the like. The word is formed from the French *houssie*, which signifies the same thing, though it anciently denoted a kind of hood worn by country people.

HOUSSA is the name of an extensive portion of Central Africa, which, along with Bornou, bears the general name of Soudan, or Land of the Blacks. It consists of various petty kingdoms or states, which occupy territory stretching east and west from the upper course of the Yeou nearly to the Niger, but the boundaries of which on the south and north are imperfectly defined. This region appears in several respects to be superior to the countries on either side of it. It is less sultry, an advantage which it probably owes to its higher elevation. The face of the country bears marks of greater cultivation, the fields being covered with large crops of wheat, two of which are annually produced; and, to prevent the grain from being destroyed by insects, it is secured in granaries raised on poles. The soil is well watered by the river Quarrama or Zirmie, which, with several tributaries, flows westward to join the Niger. On its eastern quarter it is traversed by the Yeou, and on its southern by the Shary or Tschadda, which also falls into the Niger. Besides these natural supplies of water, artificial irrigation is diligently practised. The predominant people here are the Fellatahs, of whom we shall afterwards speak.

From information afforded by Major Denham, who travelled in this region of Africa, it appears that Houssa is divided into seven provinces or states, to each of which a prince or petty governor was appointed under the Fellatahs, the inhabitants all speaking one language. Over the whole a sultan holds supreme rule. The most fertile province is Kano, the most extensive is Zegzeg, the most warlike Ghoober and Zamfra, which two countries seem to constitute one province under the rule of the Fellatahs; the central province is Kashna or Kassina. Three others, of which our information is very indistinct, are designated Dor or Dowry, Ranoo, and Yarcem. Captain Clapperton mentions a province called Guari, which may correspond to Yareem; and the same traveller speaks of Doura, in immediate connection with the southern part of Zegzeg, as if bordering on it. Another province is called Kotongra or Kotongkora, which may correspond to Ranoo.

Kano, the capital of a province of the same name, and the principal commercial city of Houssa, is situated in latitude 12° 0′ 19″ north, and longitude 9° 20′ east. It may contain between 30,000 and 40,000 inhabitants, of whom a great proportion are slaves. This number is exclusive of strangers, who crowd thither during the dry months from all parts of Africa. The city is of an irregular oval shape, about fifteen miles in circumference, and surrounded by a clay wall thirty feet in height, having a dry ditch on both sides of it. There are fourteen gates made of wood, and covered with sheet iron, and these are regularly opened and shut at sunrise and sunset. A platform inside, with two guard-houses below it, serves to defend each entrance. The houses within the walls do not occupy more than one fourth of the ground enclosed, the remaining space being laid out in fields and gardens. The city is almost divided into two parts by a large morass, which stretches from east to west. This swamp is crossed by a small neck of land, which is overflowed during the rainy season, but in the dry season the market is held upon it. On account of this morass, and also of the many pools of stagnant water made by digging clay for building houses, the city is rendered very unhealthy. Captain Clapperton thus describes the houses of Kano.

"They are built of clay, and are mostly of a square form, in the Moorish fashion, with a central room, the roof of which is supported by the trunks of palm-trees, where visitors and strangers are received. The apartments of the ground-floor open into this hall of audience, and are generally used as store-rooms. A staircase leads to an open gallery overlooking the hall, and serving as a passage to the chambers of the second story, which are lighted with small windows. In a back court-yard there is a well and other conveniences. Within the enclosure in which the house stands, there are also a few round huts of clay, roofed with the stalks of Indian corn, and thatched with long grass. These are usually very neat and clean, and of a much larger size than those of Bornou. The governor's residence covers a large space, and resembles a walled village. It even contains a mosque, and several towers three or four stories high, with windows in the European style, but without glass or frame-work. It is necessary to pass through two of these towers in order to gain the suite of inner apartments occupied by the governor."

The great market, as already observed, is held upon a neck of land which intersects the morass. Here streets consisting of sheds or stalls of bamboo are regularly arranged, different places being allotted to those who traffic in different commodities. The latter consist of cattle, vegetables, fruits, the fine cotton fabrics of the country, goora or kolla nuts, which are called African coffee, and crude antimony, with which every eyebrow in Houssa is dyed. The Arabs also dispose of sundry commodities, such as cast-off dresses. The slaves, who constitute the staple article of trade, have a special market appropriated to them, consisting of two long ranges of sheds, one for males and the other for females. Here these poor creatures, drawn up in regular array, and dressed in attractive attire, are inspected and scrutinized by purchasers, in much the same manner as horses are in the cattle-markets of this country. The market of Kano is under the superintendence of a sheik, who regulates the police, and is said also to possess the exorbitant power of fixing the prices. The medium of exchange consists of the small shells called cowries, four hundred and eighty of which make a shilling, so that paying a large sum is here rather a tedious process. Kano is celebrated all over Central Africa for the dyeing of cloth, for which process there are numerous establishments. Some ingenuity is displayed in the manufacture of leathern jars, which are fashioned upon a clay mould out of the raw hide. The inhabitants are also acquainted with the art of tanning. The negroes here are very polite and ceremonious, especially to those advanced in years. A part of the city is appropriated to the use of those who are afflicted with blindness, which is a prevalent disease.

Adjoining the province of Kano on the west there is a portion of territory called Katagum, which is said by Captain Clapperton to be a distinct province. According to that traveller, it is able to send into the field 4000 horse and 20,000 foot, armed with bows, swords, and spears. The city is built in the form of a square, the sides facing the cardinal points of the compass, with four corresponding gates, which are regularly opened and shut like those of Kano. It is defended by two walls, which have ditches on each side, and one between them. The governor and principal inhabitants have houses made entirely of clay. They are flat roofed, and sometimes consist of two stories, with square or semicircular openings for windows. The city may contain from 7000 to 8000 inhabitants. There are other towns comprised within the boundaries of this province, but none requiring particular description. Many parts of Katagum are highly cultivated, and laid out in plantations of cotton, tobacco, and indigo, which are separated from one another by rows of date-trees, and shaded by large umbrageous trees.

The next considerable town is Soccatoo, situated nearly at the western extremity of Houssa. The country which lies between Kano and Soccatoo is remarkably fine, and under high cultivation. It is diversified with forests of noble trees, and various rivers and streams, and traversed by picturesque ridges of granite, amongst which villages are romantically situated.

Soccatoo stands in latitude 13° 4′ 52″ north, and longitude 6° 12′ E. "It occupies," says Captain Clapperton, "a long ridge which slopes gently towards the north, and appeared to me the most populous town I had visited in the interior of Africa; for, unlike most other towns in Houssa, where the houses are thinly scattered, it is laid out in regular well-built streets. The houses approach close to the walls, which were built by the present sultan in 1818, after the death of his father; the old walls being too confined for the increasing population. This wall is between twenty and thirty feet high, and has twelve gates, which are regularly closed at sunset. There are two large mosques, including the new one at present building by the Gadado, besides several other places for prayer. There is a spacious market-place in the centre of the city, and another large square in front of the sultan's residence. The dwellings of the principal people are surrounded with high walls, which enclose numerous coozees and flat-roofed houses, built in the Moorish style, whose large water-spouts of baked clay, projecting from the eaves, resemble at first sight a tier of guns. The inhabitants are principally Fellatahs, possessing numerous slaves. Such of the latter as are not employed in domestic duties reside in houses by themselves, where they follow various trades; the master, of course, reaping the profit. Their usual employments are weaving, house-building, shoe-making, and iron work: many bring fire-wood to the market for sale. Those employed in raising grain and tending cattle, of which the Fellatahs have immense herds, reside in villages without the city. It is customary for private individuals to free a number of slaves every year, according to their means, during the great feast after the Ramadan. The enfranchised seldom return to their native country, but continue to reside near their old masters, still acknowledging them as their superiors, and presenting them yearly with a portion of their earnings. The trade of Soccatoo is at present inconsiderable, owing to the disturbed state of the surrounding country. The necessaries of life are very cheap; butcher-meat is in great plenty, and very good. The exports are principally civet, and blue check tobes called *sharie*, which are manufactured by the slaves from Nyffee, of whom the men are considered as the most expert weavers in Soudan, and the women as the best spinners. The common imports are brought from the borders of Ashantee; and coarse calico and woollen cloth, in small quantities, with brass and pewter dishes, and some few spices, from Nyffee. The Arabs, from Tripoli and Ghadamis, bring unwrought silk, ottar of roses, spices, and beads. Slaves are both exported and imported. A great quantity of Guinea corn is taken every year by the Tuaricks, in exchange for salt. The market is extremely well supplied, and is held daily from sunrise to sunset. On the north side of Soccatoo there is a low marsh, with some stagnant pools of water, between the city and the river: this, perhaps, may be the cause of the great prevalence of ague, as the city stands in a fine airy situation."

Subsequently to the writing of the above description, nearly two thirds of the city were destroyed by a conflagration; but when Clapperton visited it a second time, it had been rebuilt, in a manner so closely resembling what it had formerly been, that little alteration could be perceived. The palace, or house of the sultan, forms a sort of enclosed town, with an open quadrangle in front. A painted and ornamented cottage constitutes the hall of audience. Soccatoo is likely to decline, on account of the residence of the court having of late been transferred to Magaria.

The countries of Ghoober and Zamfra or Zanfara are inhabited by a rude and warlike race, who have sometimes assumed authority over Houssa, and are at present, or were lately, in open rebellion against Soccatoo. The people are a species of outlaws or robbers, and the high road between Kano and Soccatoo passing through their territory, merchants can only travel between the two cities in numerous armed bodies. Coonia, the capital of Ghoober, is strongly fortified, and in 1829 repulsed the whole military force of Houssa, consisting of 50,000 or 60,000 men. Zirmie, the capital of Zamfra, occupies a peninsula formed by the river Quarrama, which has here very high and steep banks covered with mimosas and prickly bushes, through which a narrow path winds to the gates. It is surrounded with a clay wall and a dry ditch. The governor of this stronghold bears the character of a freebooter, and the inhabitants, whom Clapperton represents as having a reckless independent look, are esteemed the greatest rogues in all Houssa. Runaway slaves from all quarters make Zirmie an asylum, where they are always well received.

To the north of Kano lies the considerable province of Kashna or Kassina, which at one period held supreme sway over all Houssa, and which has recently shaken off the yoke of Soccatoo. Kashna, the capital, is situated in lat. 12. 59. N. on a ridge of sienite, one of a number of ridges of this rock which run from north-north-east to south-south-west. The walls are of clay, and very extensive; but, as in the case of Kano, the houses do not occupy above one tenth of the ground enclosed, the rest being laid out in fields, and covered with wood. The houses are mostly in ruins, the principal commerce of the country having been transferred to Kano since the Fellatah power became predominant. Notwithstanding its abject state, it has nevertheless a considerable trade, which is carried on with the Tuaricks, or with caravans coming across the desert by the route of Ghadamis and Tuat. The manufactures of Kashna are chiefly of leather, such as water-skins, red or yellow cushions, bridles of goat-skin, and hides. There is likewise some trade in fruits, such as figs, melons, pomegranates, and limes.

To the south of Soccatoo and Kano lies the country of Zegzeg, one of the finest in all Africa, and the most extensive province in Houssa. It is bounded on the east by Kano, on the south-east by Yacoba, on the south by a mountainous tract inhabited by Pagans, on the south-west by Nyffee, and on the north and west by Guari and Kashna. Travellers represent Zegzeg as resembling in appearance the finest parts of England, being beautifully variegated with hill and dale, over which are spread rich pastures and extensive fields, yielding plentiful crops, particularly of rice. Zaria, the capital, is situated in lat. 10. 59. N. and long. 8. 42. E. It occupies a great extent of ground, the houses being detached, or rather clustered together in small villages, which are separated from each other by corn fields, and even woods. The whole is surrounded with high clay walls, and the population has been estimated at about 50,000. To the south of Zegzeg, the country, though diversified by rising grounds, is fertile and well cultivated, and contains a number of considerable towns. Lander describes Cuttup as consisting of "nearly five hundred villages almost joining each other, occupying a vast and beautiful plain, adorned with the finest trees. Among these, the plantain, the palm, and the cocoa-nut tree were seen flourishing in great abundance, and the aspect of the country strikingly resembled some parts of Yariba. A considerable traffic is carried on here in slaves and bullocks, which are alike exposed in the daily market. The bullocks are bred by the Fellatahs, who reside here for no other purpose. Among the other articles brought here for sale, are red cloth, gum, salt, goora-nuts, trona, beads, tobacco, native cloth, rings, needles, cutlery, honey, rice, and milk; people from the most distant parts resorting hither in vast numbers." To the south of this place stretch a range of hills, which, Lander was told, were inhabited by a ferocious race of *yamyams* or cannibals, who a short time previously had killed and eaten a whole caravan-full of people. In a country fertile, but rocky, is situated Dunrora, a town containing about 4000 inhabitants. Not far from this place is a large town called Jacoba, which was described to Lander as standing on the river Shary; whilst farther to the east, on the same stream, there was said to be situated another large city called Adamowa; and here our knowledge of this portion of Africa becomes scanty and imperfect.

In the western tracts of Houssa there are few towns of any importance: these were visited, and have been described, by Captain Clapperton. After leaving Boogawa, a small town in the province of Katagum, and passing first through a thickly-wooded tract, and then over an open, well-cultivated country, this traveller reached Katungwa, a walled town. A range of low rocky hills was seen stretching nearly south-west, called *Dooshee* (the rocks), from which a large town takes its name. These were the first rocks that had occurred after leaving the southern borders of the Great Desert, the whole country thus far being soft alluvial clay. Near the extremity of the Dooshee hills is situated Zangeia, within the walls of which town there is a ridge of loose blocks of stone connected with the range. These masses of rock are about 200 feet in height, and give a romantic appearance to the neat huts clustering round the base, and to the fine plantations of cotton, tobacco, and indigo, and the rows of date and other trees. From the extensive walls which remain, Zangeia must have once been a very large town. Now, however, it consists merely of a collection of thinly-scattered hamlets. The country between this place and Kano is highly cultivated, and beautifully diversified by hill and

H den.

dale. Captain Clapperton passed several walled towns, the principal of which was Girkwa. As in the other towns already described, the houses here are in groups, with large intervening vacancies. The disproportion in the size of the walls of towns and the number of houses, to the amount of inhabitants, which is exhibited in many parts of Houssa, is to be accounted for by the usurpation of the country by the Fellatahs, who generally massacred the former occupants, or carried them away captives. To complete our description of Houssa, it will be necessary to give an account of this singular people, who are gradually extending their authority over Central Africa.

By the most correct accounts, it would appear that the Fellatahs are an off-shoot from the Foolahs of Western Africa, and may be identified with them. They are a mixture of Moors, Arabs, Berbers, and probably other races of men. They are much superior to the native negroes, with whom they very rarely mix their blood. Captain Lyon, speaking of the Fellatahs, observes, " their complexion being of a much lighter hue than that of the other tribes, they call themselves white ; their colour resembles that of our gypsies in England. Many female slaves are brought to Mourzouk from their nation, and are very handsome women." Other observers describe their complexion as being very dark, and of a shade intermediate between that of the deepest African and the Moors. The fact seems to be, that their colour varies in a very remarkable manner, from being nearly white to nearly black. Both men and women pay considerable attention to their dress, which amongst the wealthy inhabitants is rather showy. In their domestic habits they are regular, orderly, and cleanly, and the slaves are generally well treated. The Mahommedan is the predominant religion, and considerable attention is paid to keeping up an appearance of it. Prayers are regularly said five times a day in the Arabic language, which both the male and female children of the better sort of Fellatahs are taught to read and write. Their marriages are celebrated without any pomp or noise, and such contracts are of a less arbitrary nature than we find them to be amongst the inferior races of mankind. Captain Clapperton makes the following remarks regarding Houssa :—" The government of the Fellatahs in Soudan is in its infancy. The governors of the different provinces are appointed during pleasure ; and all their property, on their death or removal, falls to the sultan. The appointment to a vacancy is sold to the highest bidder, who is generally a near relation, provided that his property is sufficient to enable him to bid up to the mark. All the inferior offices in the towns are sold in like manner by the governors, who also succeed to the property of those petty officers at their death or removal. In the province of Kano they have no regular system of taxation. A great deal of marketable property is claimed by the governor, such as two thirds of the produce of all the date-trees and other fruit-trees, the proprietor being allowed only the remaining third. A small duty is also levied on every article sold in the market; or, in lieu thereof, a certain rent is paid for the stall or shed. A duty is also fixed on every *tobe* that is dyed blue, and sold. On grain there is no duty. Kano produces the greatest revenue that the sultan receives ; it is paid monthly, in horses, cloth, and cowries. Adamowa pays yearly in slaves ; Yacoba in slaves and lead ore ; Zegzeg in slaves and cowries ; Zamfra the same ; Hadiga, and Katagum, and Zaonima in horses, bullocks, and slaves ; Kashna in slaves, cowries, and cloth ; Ader, or Tadela, in bullocks, sheep, camels, and a coarse kind of cotton cloth, like what is called by us a counterpane." Of the number of negroes and Fellatahs who inhabit the country of Houssa no correct idea can be formed. (R. R. R.)

Howard.

HOVEDEN, Roger de, descended of an illustrious family, was born in Yorkshire, most probably at the town of that name, some time in the reign of Henry I. After he had received the rudiments of education in his native country, he studied the civil and canon law, which were fashionable and lucrative branches of learning. He became domestic chaplain to Henry II. who employed him to transact several ecclesiastical affairs, in the conduct of which he acquitted himself with honour. He was by profession a lawyer, but, like other lawyers of the time, belonged to the church, and also officiated as professor of theology at Oxford. After the death of Henry, he applied himself to history, and composed annals, which commence at the year 731, where Bede's ecclesiastical history terminates, and extend to the third year of King John, or 1202. These annals were first published by Saville, amongst the *Historici Anglici*, 1595, and were reprinted at Frankfort, 1601, in two books, folio. The style of Hoveden is barbarous, like the age to which it belongs ; but in diligence, knowledge of antiquity, and that fidelity which is the first quality of an historian, he not only surpassed the rude historians of the preceding ages, but left an example which many of his successors, in more enlightened times, failed to imitate. According to Vossius, Hoveden also wrote a history of the Northumbrian kings, and a life of Thomas à Becket. Edward III. when endeavouring to ascertain his title to the crown of Scotland, caused a diligent search to be made for the works of Hoveden ; a circumstance which shows the estimation in which they were held, not only by the monarch himself, but by the age in which he flourished. (A.)

HOWARD, Henry, Earl of Surrey, a highly-accomplished nobleman, the son and grandson of two Dukes of Norfolk, was born about the year 1520, and educated in Windsor Castle, with Henry Fitzroy, earl of Richmond, natural son of King Henry VIII. Wood states from tradition that he was for a time a student at Cardinal College, Oxford. In 1532, Howard, with his companion Richmond, was at Paris, where he remained a number of months. The latter died in 1536, after which Howard travelled into Germany, where he visited the emperor's court, and thence proceeded to Florence, where he fell in love with the fair Geraldine, whom his sonnets have immortalized, and, like a true *innamorato*, published a challenge to all comers, whether Christians, Jews, Saracens, Turks, or cannibals, in defence of the beauty of his mistress, and proved victorious in the tournament instituted by the grand duke on the occasion. The duke, it seems, was so delighted with his gallant exploits, that he would gladly have retained him at his court ; but he rejected the invitation, being determined to maintain the superlative beauty of his Geraldine in all the principal cities in Italy. This romantic resolution was however frustrated by the command of his sovereign, Henry VIII. recalling him to England.

In 1540 he signalized himself in a tournament at Westminster, against Sir John Dudley, Sir Thomas Seymour, and others. In 1542 he marched under the command of his father against the Scotch ; and in the same year he was confined in Windsor Castle for eating flesh in Lent, contrary to the king's proclamation. In the expedition to Boulogne in France, he was in 1544 appointed field-marshal of the English army ; and after the taking of that town in 1546, made king's lieutenant and captain-general of the forces in France. He was at this time knight of the Garter. In the same year, having attempted to intercept a convoy, he was defeated by the French, and soon afterwards superseded in his command by the Earl of Hertford.

After his return to England, Surrey, conscious of his former services, and peevish under his disgrace, could not help reflecting on the king and council. This proved the first step towards his destruction. He had married Frances, the daughter of John earl of Oxford ; and after her death he is said to have made love to the Princess Mary. For this the Seymours, rivals of the Norfolk family, and now in favour with the king, accused him of aspiring to the crown, adding, that he had already presumed to quarter part of the royal arms with his own; but, whatever might be the pretence, the real cause of his ruin was the jealousy and power of his enemies. In short, the destruction of the Howards being determined on, Surrey, and his father the Duke of Norfolk, were committed to the Tower, on the 12th of December 1546; and on the 13th of January following, Surrey was tried at Guildhall by a common jury, and beheaded on Tower-Hill on the 19th day of the same month, nine days before the death of the king, who thus, to fill up the measure of his crimes, finished his life with the murder of his best subject. The accusations brought against this young nobleman on his trial were so exceedingly ridiculous, that one is astonished how it was possible, even in that despotic reign, to find a judge and jury so unprincipled as to carry on the farce of a trial and conviction.

As to the character of this unfortunate nobleman, all our poets have celebrated his praise. Mr Walpole commences his anecdotes of Surrey by observing: "We now emerge from the twilight of learning to an almost classic author, that ornament of a boisterous yet not unpolished court, the Earl of Surrey, celebrated by Drayton, Dryden, Fenton, Pope, illustrated by his own muse, and lamented for his unhappy death; a man, as Sir Walter Raleigh says, no less valiant than learned, and of excellent hopes." Leland calls him the conscript enrolled heir of Sir Thomas Wyatt the elder, in his learning and other excellent qualities; and the author of *The Art of English Poetry* says, that the Earl of Surrey and Sir Thomas Wyatt may justly be called the reformers of our poetry and style. His poems were published in 1557, 12mo; and in 1565, 1574, 1585, 1587, 8vo. Several of the sonnets ascribed to him are by Sir Thomas Wyatt and others. He also translated two books of the Æneid, which he executed with fidelity without prosaic servility, and which form the earliest specimen of blank verse in the English language. The diction is often poetical, and the versification varied by suitable pauses. It is probable that he intended to translate the whole; and this is so much more correct and elegant than his other translations, that it appears to have been the production of his happier days.

Howard, *Charles*, an able statesman and experienced seaman, was the son of Lord William Howard, baron of Effingham, and born in 1536. He served under his father, who was lord high admiral of England, till the accession of Queen Elizabeth. In January 1573 he succeeded his father in his title and estate; after which he became successively chamberlain of the household and knight of the Garter, and in 1585 was made lord high admiral, at the critical juncture when the Spaniards were sending an Armada, as they supposed, to the assured conquest of this kingdom. When he received intelligence of the approach of the Spanish fleet, and saw of how great consequence it was to get out the few ships which were ready at Plymouth, he not only gave orders in every thing himself, but even wrought with his own hands, and the first night left the port with six ships. The next morning, though he had only thirty sail, and these the smallest of the fleet, he attacked the Spanish fleet; but first despatched his brother-in-law, Sir Edward Hobby, to the queen, to desire her majesty to make a proper disposition of the land forces for the security of the coast, and to hasten as many ships as possible to his assistance. His valour was conspicuously displayed in repeated attacks of a superior enemy. The coolness of his temper was not less remarkable; and it was owing to his energy and prudence that the victory remained with the English. The queen expressed her sense of his merit in the most honourable terms, and granted him a pension for life. In 1596 he commanded in chief the naval, as Essex did the land, forces sent against Spain, when, in the attack on Cadiz, his prudence and moderation were amongst the principal causes of the success which the English met with in that great and glorious enterprise; and, upon his return the following year, he was advanced to the dignity of Earl of Nottingham. The next eminent service in which his lordship was engaged was in 1599, when the Spaniards seemed to meditate a new invasion. Her majesty, who always placed her safety in being too quick for her enemies, drew together, in a fortnight, a fleet and an army, which rendered hopeless the success of her foreign and domestic enemies; and she gave the earl the supreme command of both, with the title of lord-lieutenant-general of all England, an office unknown in succeeding times. When age and infirmity had unfitted him for action, he resigned his office, and spent the remainder of his life in ease and retirement till the period of his decease, which happened in 1624, in the eighty-seventh year of his age.

Howard, *John*, a man of singular and transcendent humanity, was the son of a reputable tradesman in St Paul's Churchyard, and was born at Hackney in the year 1726. At a proper age he was put as apprentice to Mr Nathaniel Newnham, a wholesale grocer in Watling Street. But not long after this, his father died, leaving only this son and a daughter, to both of whom he bequeathed handsome fortunes; and by his will he directed that his son should not be considered as of age till he had reached five-and-twenty. His constitution was weak, and his health appeared to have been injured by the necessary duties of his apprenticeship; and therefore, at its expiration, he took an apartment in a lodging-house in Church Street, Stoke Newington, Middlesex; but not meeting with the tenderest treatment, he removed to another lodging-house in the same street, which was kept by a widow lady, Mrs Sarah Lardeau, a worthy sensible woman, but an invalid. Here he was nursed with so much care and attention, that out of gratitude for her kindness, he resolved to marry his landlady. In vain did the latter expostulate with him upon the extravagance of such a proceeding, considering the disparity of their ages; but nothing could alter his resolution, and they were privately married about the year 1752. This lady was possessed of a small fortune, which he presented to her sister. During his residence at Newington, the minister of the dissenting meeting-house in that place resigned his office, when a successor was appointed; and Mr Howard, who was bred a dissenter, and all his life stedfastly adhered to that profession, proposed to purchase the lease of a house near the meeting-house, and to appropriate it as a parsonage-house for the use of the minister for the time being, for which purpose he contributed L.50. His wife died on the 10th of November 1755, aged fifty-four; and he was a sincere and affectionate mourner for her death. About this time, it is believed, he was elected a fellow of the Royal Society. In the year 1756 he had the misfortune to experience some of the evils which it afterwards became the business of his life to alleviate. Having embarked that year in a Lisbon packet, the Hanover, in order to make the tour of Portugal, the vessel was taken by a French privateer; and the hardships he suffered during his subsequent confinement in France are naturally supposed to have awakened his sympathies in favour of prisoners, and to have suggested to him the humane enterprise of endeavouring to render prisons less pernicious to health and morality. "Before we reached Brest," says he (*On Prisons*, 4to, 1784, p. 11), "I suffered the extremity of thirst, not having for above forty hours one drop of water, nor hardly a morsel of food. In the castle at Brest I lay six nights upon straw; and observing how cruelly my countrymen were used there and at Morlaix, whither I was carried next, during the two months I was at Carhaix upon parole, I corresponded with the English prisoners at Brest, Morlaix, and Dinnan; at the last of those towns were several of our ship's crew, and my servant. I had sufficient evidence of their being treated with such barbarity, that many hundreds had perished, and that thirty-six were buried in a hole at Dinnan in one day. When I came to England, still on parole, I made known to the commissioners of sick and wounded seamen the sundry particulars, which gained their attention and thanks. Remonstrance was made to the French court; our sailors had redress; and those that were in the three prisons mentioned above were brought home in the first cartel ships. Perhaps," adds Mr Howard, "what I suffered on this occasion increased my sympathy with the unhappy people whose case is the subject of this book."

He afterwards, it is said, made the tour of Italy; and at his return settled at Brokenhurst, a retired and pleasant villa in the New Forest, near Lymington, in Hampshire, having, on the 25th of April 1758, married a daughter of Edward Leeds of Croxton, Cambridgeshire, king's serjeant. This lady died in 1765, in giving birth to her only child, a son, who unfortunately became lunatic. After her death Mr Howard left Lymington, and purchased an estate at Cardington, near Bedford.

But the sphere in which he had hitherto moved was too narrow for his enlarged mind. Being named in 1773 to the office of sheriff of Bedfordshire, from that time his sphere of usefulness was extended. His office, as he himself observes, brought the distress of prisoners more immediately under his notice. A sense of duty induced him personally to visit the county jail, where he observed such abuses and scenes of calamity as he had before no conception of; and he soon exerted himself in order to reform them. With a view to obtain precedents for certain regulations which he proposed, he went to inspect the prisons in some neighbouring counties. But finding in them equal room for complaint and commiseration, he determined to visit the principal prisons in England. The farther he proceeded, however, the more shocking were the scenes presented to his view; and this induced him to resolve upon exerting himself to the utmost, in order to effect a general reform in these horrid places of confinement, considering it as of the highest importance, not only to the wretched objects themselves, but to the community at large. Upon this subject he was examined by the House of Commons in March 1774, when he had the honour of receiving their thanks. This encouraged him to proceed in his design. He revisited all the prisons in the kingdom, together with the principal houses of correction. He also in 1775 enlarged his circuit by going into Wales, Scotland, and Ireland, where he found the same want of reformation.

One grand object which he had in view was, to put a stop to that shocking distemper called the jail fever, which raged so dreadfully in many of the prisons as to render them to the last degree offensive and dangerous; a distemper by which more had been taken off than by the hands of the executioner, and which, in several instances, had been communicated from the prisons into the courts of justice, and proved fatal to the magistrates and judges, and to multitudes of persons who attended the trials, as well as to the families of discharged felons and debtors. Another end he proposed was, to procure the immediate release of prisoners, who, upon trial, were acquitted, but who often continued to be unjustly detained from not being able to pay the accustomed fees; and also to abolish many other absurd and cruel usages which had long prevailed. But the great object of all was, to introduce a thorough reform of morals into our prisons, where he had found the most flagrant vices prevailing to such a degree, that they were become seminaries of wickedness and villany, and the most formidable nuisances to the community, in consequence of the promiscuous intercourse of prisoners of both sexes, and of all ages and descriptions, by which the young and less experienced were initiated, by old and hardened sinners, into all the arts of villany and the mysteries of iniquity; so that, instead of being reformed by their confinement, which should be the chief end of punishment, those who were discharged became more dangerous to society than before.

These laudable endeavours he had the satisfaction to see, in some instances, crowned with success; particularly in regard to the healthiness of prisons, some of which were rebuilt under his inspection. Through his interposition, also, better provision was made for the instruction of prisoners, by the introduction of bibles and other pious books into their cells, and a more constant attendance of clergymen. But in order to introduce a more general and humane regulation, and to conduce to the reformation of criminals, he determined to visit other countries, and examine the plans there adopted, in the hope of collecting some information which might be useful in his own country. For this purpose he travelled into France, Flanders, Holland, Germany, and Switzerland, and afterwards through the Prussian and Austrian dominions. He also visited the capitals of Denmark, Sweden, Russia, and Poland, and some cities in Portugal and Spain. In all these expensive and hazardous journeys, he denied himself the usual gratifications of travellers, and declined the honours which were offered him by persons of the first distinction, applying himself solely to one grand object. To him indeed the inspection of a jail, or an hospital, was more grateful than all the entertainments of a palace. With what astonishment and gratitude he was received by their miserable inhabitants may easily be imagined, since, whilst he made observations on their situation, he meditated their relief; and many distressed prisoners abroad, as well as at home, partook of his bounty, and some were liberated by it; for he considered those of every nation, and people, and tongue, as brethren. On his return, he published, in 1777, the State of the Prisons in England and Wales, with Preliminary Observations, and an Account of some Foreign Prisons, 4to. In the year 1778 he undertook a third journey through the Prussian and Austrian dominions, and the free cities of Germany; and likewise extended his tour through Italy, and revisited some of the countries which he had before examined. The observations he made in this tour were published in an appendix, 1780, containing also some remarks respecting the management of prisoners of war, and the hulks on the Thames. But wishing to acquire some further knowledge on the subject, he, in 1781, revisited Holland and some cities in Germany. He also visited the capitals of Denmark, Sweden, Russia, and Poland, and in 1783 some cities in Portugal and Spain; and returned through France, Flanders, and Holland. The substance of all these travels was afterwards thrown into one narrative, which was published in the year 1784. He likewise published a curious account of the Bastille, in 8vo.

His travels and exertions, however, were not yet at an end. He conceived a further design, which was to visit the principal lazarettos in France and Italy, in order to procure information concerning the best methods of preventing the spread of the plague, with a view to apply them to other infectious disorders. But not obtaining all the satisfaction which he wished for in those countries, he proceeded to Smyrna and Constantinople, where that most dreadful of human distempers actually prevailed; "pleasing himself," as he said, "with the idea of not only learning, but of being able to communicate somewhat to the inhabitants of those distant regions." In the execution of this design, though he was so much exposed to danger, and actually caught the plague, "that merciful

Providence," as he himself piously remarks, "which had hitherto preserved him, was pleased to extend its protection to him in this journey also, and to bring him home once more in safety.". On his way home he revisited the chief prisons and hospitals in the countries through which he passed; and afterwards went again to Scotland, and thence to Ireland, where he proposed a new and very important object, namely, to inspect the Protestant charter-schools, in some of which he had before observed shameful abuses, which he reported to a committee of the Irish House of Commons. In this more extensive tour, he took a particular account of what he had observed amiss in the conduct of this noble charity, with a view to a reformation, and not without considerable success. In the course of these journeys, particular cities and communities were not unmindful of paying him proper respect. At Dublin, he was created a doctor of laws by Trinity College; and the city of Glasgow and the town of Liverpool did honour to themselves by enrolling him amongst their members. Upon his return home, having again inspected the prisons in England, and the hulks on the Thames, in order to see what alterations for the better had been made, and which he found to be very considerable, though still imperfect, he published the result of his last laborious investigations, in an Account of the Principal Lazarettos in Europe, with various Papers relative to the Plague, together with further Observations on some Foreign Prisons and Hospitals, and additional Remarks on the present State of those in Great Britain and Ireland, with a great number of curious plates. The work likewise contained observations on penitentiary houses, which had been encouraged by act of parliament, for the correction and reformation of criminals, and of which he and Dr Fothergill had been nominated by the king superintendents. Besides these, he published the Grand Duke of Tuscany's new code of criminal law, with an English translation; of which, as indeed of all his publications, he gave away a great number of copies amongst his acquaintance. His laying open the horrors of despotism in a neighbouring country, however, had nearly exposed him to suffer them; and had it not been for the timely notice of our ambassador, he would probably have ended his days in the Bastille.

Not satisfied, however, with what he had already done, he concludes his Account of Lazarettos with announcing his intention again to quit his country, for the purpose of revisiting Russia, Turkey, and some other countries, and extending his tour in the East. "I am not insensible," says he, "of the dangers that must attend such a journey. Trusting, however, in the protection of that kind Providence which has hitherto preserved me, I calmly and cheerfully commit myself to the disposal of unerring wisdom. Should it please God to cut off my life in the prosecution of this design, let not my conduct be uncandidly imputed to rashness or enthusiasm, but to a serious, deliberate conviction that I am pursuing the path of duty, and to a sincere desire of being made an instrument of more extensive usefulness to my fellow-creatures than could be expected in the narrower circle of a retired life." Accordingly, to the great concern of his friends, he set out in summer 1789 on this hazardous enterprise; the principal object of which was to administer a medicine in high repute at home in malignant fevers (Dr James's powder), under a strong persuasion that it would prove equally efficacious in the plague. But in this second tour in the East, it pleased God to cut off his life; for, having spent some time at Cherson, a new settlement of the empress of Russia, at the mouth of the Dnieper or Borysthenes, towards the northern extremity of the Black Sea, near Oczakow, he, in visiting the Russian hospital of that place, or, as some say, a young lady, caught a malignant fever, which carried him off on the 20th of January, after an illness of about twelve days; and having been kept five days, according to his express directions, he was buried, by his own desire, in the garden of a villa in the neighbourhood, belonging to a French gentleman, from whom he had received great civilities. While absent on his first tour in Turkey, his character for active benevolence had so much attracted the public attention, that a subscription was set on foot to erect a statue to his honour, and in a short time above L.1500 was subscribed for that purpose. But some of those who knew Mr Howard best never concurred in the scheme, being well assured that he would neither countenance nor accede to it; and in consequence of two letters to the subscribers, from Mr Howard himself, the design was laid aside. It was, however, resumed after his death; and surely, of all the statues or monuments raised by public gratitude to illustrious characters either in ancient or modern times, none was ever erected in honour of worth so genuine and admirable as that of Howard, who devoted his time, his strength, his fortune, and finally sacrificed his life, in the pursuits of humanity; and who, to adopt the expressive words of Mr Burke,[1] "visited all Europe [and the East], not to survey the sumptuousness of palaces or the stateliness of temples; not to make accurate measurements of the remains of ancient grandeur, nor to form a scale of the curiosity of modern art; not to collect medals, or to collate manuscripts; but to dive into the depth of dungeons; to plunge into the infection of hospitals; to survey the mansions of sorrow and of pain; to take the gauge and dimensions of misery, depression, and contempt; to remember the forgotten; to attend to the neglected; to visit the forsaken; and to compare and collate the distresses of all men in all countries. His plan is original, and it is as full of genius as it is of humanity. It is a voyage of discovery, a circumnavigation of charity; and already the benefit of his labour is felt more or less in every country."

HOWDEN, a market-town of the east riding of the county of York, 184 miles from London. It stands in a level and somewhat marshy district, about one mile from the river Ouse, over which there is a ferry. It is very ancient, and was formerly the seat of the Bishop of Durham. There is a market on Saturday, to which much corn is brought; and one of the largest fairs for horses is held in July. The population amounted in 1801 to 1552, in 1811 to 1812, in 1821 to 2080, and in 1831 to 2130.

HOWE, Richard, Earl, an English naval commander of distinguished eminence, was born in the year 1725, being the second son of Lord Viscount Howe, by the daughter of Baron Kilmansegg. From his early attachment to the life of a mariner, he quitted the school of Eton at the age of fourteen, and went on board the Severn, commanded by the Honourable Captain Legge, and destined for the South Seas under Commodore Anson. Mr Howe next appeared in the Burford, Captain Lushington commander, who being killed in an expedition against the Caraccas, Commodore Knowles made Mr Howe an acting lieutenant. At the age of twenty he was promoted to the rank of commander in the Baltimore sloop of war, and joined a squadron at that time cruising off the coast of Scotland, where he met with an opportunity of displaying his undaunted courage and intrepidity, by engaging and beating off two French frigates of thirty guns each, with the assistance of another armed ship, notwithstanding that he was severely wounded in the head during the action. This service was immediately and justly rewarded with the rank of post-captain. He was soon afterwards appointed to the rank of captain on board Commodore Knowles's own ship of eighty guns, with which he returned to England in the year 1748. When hostilities again commenced, he commanded the Dunkirk of sixty guns, in North America; a ship which constituted part of the squadron under Admiral Boscawen, and with which he captured a French man of war of superior metal, off the coast of Newfoundland, namely, the Alcide of sixty-four guns. In order to annoy the coast of France, he received in the year 1758 the command of a small squadron, with which he effected the destruction, at St Malo, of a number of magazines and ships. When he served on board the Essex, Prince Edward, afterwards Duke of York, sailed with him, at which time he powerfully contributed to the reduction of the town of Cherbourg. In 1758 his elder brother fell in North America, in the service of his king and country; upon which occasion the young commodore succeeded to the family title and estate. In the following year he had a share in the victory gained by Sir Edward Hawke over the French fleet under Admiral Conflans. He afterwards served in the Channel, and was captain of the Amelia, the ship of admiral the Duke of York. On the restoration of peace, he was nominated one of the lords of the admiralty, and some time afterwards treasurer of the navy. He was in the year 1770 raised to the rank of rear-admiral of the blue, and chosen commander-in-chief on the Mediterranean station. In 1775 he was promoted to the rank of rear-admiral of the white. In reference to his rapid promotion, Lord Hawke said in the House of Peers, "I advised his majesty to make the promotion. I have tried my Lord Howe on important occasions; he never asked me how he was to execute any service, but always went and performed it."

---

[1] Speech at Guildhall in Bristol, 1780.

In the summer of 1776, Lord Howe appeared off Massachusetts, as commander-in-chief of his Britannic majesty's fleet acting in North America, and in the capacity of commissioner for restoring the blessings of an amicable reconciliation. All the provincial governors were made acquainted with his arrival by means of circular letters expressive of the full extent of the authority with which he and his fellow commissioners were invested; but as congress did not deem the conditions which these letters contained to be at all satisfactory, they were ordered to be inserted in all the gazettes for the examination of the people. His powers being thus circumscribed at the very commencement, he could only act in the capacity of naval commander, in which he aided the operations of the land forces with uncommon skill. It was not to be imagined, however, that much glory could redound to his lordship from such an unequal contest, till the junction of France with America placed the contending parties more upon a level. On the arrival of Admiral d'Estaing, in the month of July 1778, off Sandy Hook, Lord Howe was certainly in a very critical situation; but, in consequence of an effort of uncommon skill and dexterity, the French commander deemed it prudent to retire, when he was pursued by Lord Howe to Rhode Island, after obtaining a reinforcement under Admiral Byron. The intentions of the enemy were completely counteracted, and the campaign was finally terminated with honour. Here he resigned his command, and returned to England; but in 1782 he was promoted to the rank of admiral of the blue, made a viscount of Great Britain, and chosen commander of the fleet which was sent for the relief of Gibraltar. The combined fleets of France and Spain were about a third superior to that under Lord Howe, who, with thirty-four sail of the line, appeared off Gibraltar in the month of October, being driven into the Mediterranean by contrary winds. Although he was pursued by the combined fleet, he found means to supply the fortress with provisions. He checked the enemy by a partial action, and notwithstanding he offered to give them battle, it was declined on their part; and he had the satisfaction to execute his commission prior to his return home, in spite of the numerous difficulties which he had to encounter.

On the termination of the war he was nominated first lord of the admiralty, which he both resigned and resumed with the different changes of administration. In the year 1787 he was appointed admiral of the white, and in the following year created an earl of Great Britain. When hostilities were renewed with France in 1793, his lordship, at the express desire of his majesty, accepted the command of the Channel fleet; but he had it not in his power to effect any thing decisive till the summer of 1794. On the memorable first of June, with a fleet consisting of twenty-five sail of the line, he gave battle to a French fleet of twenty-six, and gained a most signal victory over the enemy, capturing seven of their ships, one of which was so shattered as to go to the bottom, whilst several others were very much crippled. His lordship had the good fortune not to lose a ship, and comparatively but few men, considering the great loss sustained by the enemy. The gratitude of the nation was suitable to the importance of this naval victory, and it is more than probable that the first of June will never be forgotten. In 1795 he was made general of marines; but the infirmities which are the usual concomitants of age induced him to resign his naval command in the year 1797, and on his final retreat he was presented with the badge of the Garter. His influence as an officer contributed greatly to stifle a spirit of mutiny and discontent which at this time exhibited alarming symptoms amongst the seamen of his majesty's fleets. He terminated his brilliant and honourable career on the 5th of August 1799, in the seventy-third year of his age, leaving none but female issue behind him. His lordship's valour, always cool and steady, was of that nature which enables a commander to make the most of his situation; his judgment was sound and penetrating, which prevented him from being easily imposed upon by external appearances; and his seamanship was of the most consummate and masterly kind.

Howe's *Island*, in the South Pacific Ocean, discovered by Captain Wallis in 1767. It is about sixty miles long and four broad, and was found by Captain Cook in 1774 to consist of several smaller islands almost joined together by reefs, and to have no inhabitants. Long. 154. 7. W. Lat. 16. 46. S.

HOWITZ, a kind of mortar, mounted upon a field carriage, like a gun. See Gunnery.

HOWTH, a promontory which forms the northern entrance of the Bay of Dublin, having a small village about seven miles north-east from that city, in the province of Leinster. It gives the title of earl to the family of St Lawrence, who were so called from a victory obtained by them over the Irish on St Lawrence's day 1177, their former name being Tristram; and this place has continued in possession of the family above six centuries. Long. 6. 22. W. Lat. 53. 21. N.

HOY, a small vessel chiefly used in coasting, or carrying goods to or from a ship, in a road or bay, where the ordinary lighters cannot be managed with safety or convenience.

Hoy, one of the Orkney Islands, off the north coast of Scotland, is situated between the island of Pomona and the north coast of Caithness, and is separated from the small island of Græmsay by a sound about a mile in breadth. See Orkney Islands.

HOXTER, a city of Prussia, the capital of a circle of the same name, in the Minden division of the province of Westphalia. It is situated on the river Weser, and contains 460 houses, with 3411 inhabitants. The manufactures are linen, leather, and table-cloths. Long. 9. 16. 11. E. Lat. 51. 46. 42. N.

Hoya || Hucknall-Torkard.

HOYA, WITH DIEPHOLZ, a province of the kingdom of Hanover. It has been formed at different periods, a part having belonged to the house of Brunswick since the year 1583, another part which came to that house two years after, and a part consisting of three bailiwicks, which was ceded by the prince of Hesse-Cassel in 1815. It is bounded on the north-west by Oldenburg, on the north by Bremen and Brunswick, on the north-east by Bremen and Verden, on the east by Calenburg and Luneburg, on the south by Prussian Westphalia, on the south-west by Oldenburg, and on the west by Osnabruck. It extends over 1352 square miles, contains one city (Hoya), twenty-four market-towns, fifty-six parishes, and 497 villages and hamlets, and 14,666 dwellings. The number of inhabitants amounted in 1812 to 104,970, but they are estimated to have increased one fifth since that period. The Platt-Deutsche is the common language. The religion is exclusively Lutheran, or at least the Catholics and reformed are in no place so numerous as to hold any public exercise of their forms of worship. It is generally a sandy heath, but towards the river Weser there are some tolerably fertile pasture lands. It yields buck-wheat, rye, barley, and a very small portion of wheat, and produces flax, feathers, wax, and honey. The only manufactures are coarse linens and woollens, made in each peasant's house for his own family. The capital, Hoya, is situated on the Weser, and contains 220 houses and 1867 inhabitants, who carry on some trade by the river with Bremen. Long. 9. 5. 40. E. Lat. 52. 48. 47. N.

HUAHEINE, or AHEINE, signifying, in the native language of the South Sea Islands, *woman*, the easternmost of the group called the Society Islands by Captain Cook. It is twenty-four miles in circumference, and is divided into two peninsulas by an isthmus overflowed at high water. It has a very narrow stripe of fertile low land next the shore, and the hills are in some places highly cultivated. The productions are similar to those of Otaheite, but they are about a month earlier. The inhabitants are larger made and stouter, and the women are in general more handsome. This island has been visited by many navigators since the time of Captain Cook, but their information throws no new light on the productions of the island or the manners of the people. Long. 150. 58. W. Lat. 16. 43. S.

HUBELY, a town of Hindustan, in the province of Bejapoor. It is large and populous, defended by a mud rampart and ditch, and has for many years carried on an extensive trade, particularly with Goa, to which are sent sandal wood and elephants' teeth, and in return raw silk, cottons, woollens, and rice are received. There are also manufactures of raw silk and cotton, great quantities of which are sold for the dresses of the country people. It is a wealthy place, the residence of many rich bankers, who, by means of their agents, extend their commercial intercourse to Surat, Hyderabad, Seringapatam, and even to more distant places on which bills of exchange can be negotiated, and who regulate the standard of the currency in all the adjoining countries. The English East India Company formerly had a factory here, which was plundered by the Mahrattas in 1673, when the Company sustained a great loss. In 1685 it was taken by the Mogul troops of Aurungzebe, and soon after the death of that monarch in 1707 it was again taken by the Mahrattas, and still continues in their possession. Long. 75. 10. E. Lat. 15. 24. N.

HUBNER, JOHN, a learned geographer of Germany, who taught geography at Leipsic and Hamburg with extraordinary reputation; and died at Hamburg in 1732, aged sixty-three. His principal work is a Geographical Treatise, printed at Basil in 1746, in six vols. 12mo.

HUCKNALL-TORKARD, a town in the hundred of Broxtow, in the county of Nottingham, 130 miles from London, where there are manufactures of hosiery. The inhabitants amounted in 1801 to 1497, in 1811 to 1793, in 1821 to 1940, and in 1831 to 2200.

HUDDERSFIELD, an extensive town and parish in the wapentake of Aybrig, of the west riding of Yorkshire, 187 miles from London. It stands on the river Colne, and is connected by canal navigation with the Calder at Wakefield, a distance of fourteen miles. It is a place of great industry, chiefly occupied in the manufacture of woollen goods of various kinds. A cloth market is held on Tuesday, which is very numerously attended by woolstaplers and merchants from Leeds, Halifax, and Wakefield, as well as by some from Manchester, with which it has also a canal communication. A new cloth hall was built in 1765, by Sir John Ramsden, the proprietor of the site of the town, and it is a very fine building. The inhabitants amounted in 1801 to 7268, in 1811 to 9671, in 1821 to 13,284, and in 1831 to 19,035. It has been created a borough by the law of 1832, returns one member to parliament, and has about 600 voters.

HUDSON, HENRY. Of this eminent navigator nothing is known prior to the year 1607, when he was employed by some London merchants in a small vessel, for exploring a north-east passage to China and Japan. He set sail on the 1st of May with only ten men and a boy, and reached as high as 80° of north latitude, where being stopped by the ice, he returned to England in the month of September following. In his next voyage he landed at Nova Zembla; but being unable to make any farther east, he returned in August the following year. The Dutch East India Company fitted him out in the year 1609, with a crew of twenty men, English and Dutch; and after attempting in vain to penetrate eastward, he steered for the American coast, and went as far as Chesapeake Bay. But his crew having mutinied, he durst not attempt a westerly passage through Davis's Strait, and therefore returned home. The knowledge acquired by him in these voyages increased his ardour for discovery, and he again made an offer of his services to the Dutch East India Company, which were not accepted; and for his last voyage, Sir Thomas Smith, Sir Dudley Digges, and some other of his friends, fitted him out. He set sail on the 17th of April, and came in sight of Greenland on the 4th of June. Sailing westward, he reached the mouth of the strait which bears his name, through which he advanced along the coast of Labrador, which he called *Nova Britannia*. Here he hoped to have discovered the long-wished-for passage; but he found he was only in a bay, in the southern part of which he determined to winter. After this he fitted out his shallop for further discoveries; but as he had no means of revictualling his ship, he distributed his last remaining bread, with tears in his eyes, amongst his people, and proposed to return home. But his mutinous crew entered his cabin by night, tied his hands behind his back, and set him ashore at the west end of the straits, with seven of the crew who were most attached to him. They were never more heard of, and it is probable that they were swallowed up by the waves.

HUDSON, *William*, a celebrated English botanist, was born at Westmoreland about 1730. He was bound apprentice to an apothecary in London, whose business he continued, and proved a friend to the widow and daughters of his master. It appears from the testimony of Dr Pulteney, that he had a residence in the British Museum, but we are not informed in what capacity. He died of a paralytic distemper in May 1793. He possessed a comprehensive knowledge of English plants, which induced him to undertake an arrangement of English botany according to the Linnæan classification; a task which had been previously attempted by Dr Hill, but the execution lson's ay | lson's ver.

of which was very imperfect. Hudson's *Flora Anglica* appeared in 1762, in one volume 8vo, the Latin preface to which was written by Mr Stillingfleet, received with great applause, and contributed greatly to the adoption of the sexual system in England.

HUDSON's Bay, a large bay of North America, lying between 51 and 69 degrees of latitude, discovered in 1610 by Henry Hudson. This intrepid mariner, in searching after a north-west passage to the South Seas, discovered three straits, through which he hoped to discover a passage to Asia by America. He had made two voyages before on the same adventure; the first in 1607, and the second in 1608. In his third and last, 1610, he entered the straits leading into this new Mediterranean, the bay known by his name; coasted a great part of it, and penetrated to eighty degrees and a half into the heart of the frozen zone. His ardour for the discovery not being abated by the difficulties he struggled with in this domain of winter, he staid there until the ensuing spring, and prepared in the beginning of 1611 to pursue his discoveries; but his crew, who had suffered equal hardships, without the same spirit to support them, mutinied, seized upon Hudson and seven of those who were most faithful to him, and committed them to the fury of the arctic seas in an open boat. As already mentioned, Hudson and his companions were either swallowed up by the waves, or, gaining the inhospitable coast, were destroyed by the savages; but the ship and the rest of the men returned home. Other attempts towards a discovery were made in 1612 and 1667; and a patent for planting the country, with a charter for a company, was obtained in the year 1670. In 1746 Captain Ellis wintered as far north as fifty-seven degrees and a half; and Captain Christopher attempted further discoveries in 1761. The company being desirous of obtaining information regarding a river called the Coppermine River, directed Mr Hearne, a young gentleman in their service, to proceed over land for that river, which he had orders to survey if possible down to its embouchure; to make observations for fixing the latitudes and longitudes; and to bring home maps and drawings both of it and the countries through which he might pass. Accordingly Mr Hearne set out from Prince of Wales's Fort, on Churchill River, latitude 58° 47½' north, and longitude 94° 7½' west from Greenwich, on the 7th of December 1770. On the 13th of June he reached the Coppermine River, and found it all the way, even to its mouth, encumbered with shoals and falls, and emptying itself into the sea over a dry flat of the shore, the tide being then out, which seemed by the edges of the ice to rise about twelve or fourteen feet. Mr Hearne was nevertheless sure of the place where it emptied itself into being the sea, or a branch of it, by the quantity of whalebone and seal-skins which the Esquimaux had at their tents, and also by the number of seals which he saw upon the ice. It appears from the map which Mr Hearne constructed of this singular journey, that the mouth of the Coppermine River lies in latitude 72° north, and longitude 25° west from Churchill River; that is, about 119° west of Greenwich. Mr Hearne's journey back from the Coppermine River to Churchill lasted till the 30th of June 1772, so that he was absent about a year and seven months. The subsequent progress of discovery in this quarter has been detailed in the article on GREENLAND.

HUDSON's Bay Company. See COMPANY.

HUDSON's River, a large river of North America, which rises on the east of Lake Ontario, and running by Albany, and on the back of the south part of New England through part of New York, falls into the bay of the sea beyond the west end of Long Island, and below the town of New York.

Hue and Cry || Huet.

HUE AND CRY, in *Law*, the pursuit of a person who has committed felony on the highway. Of this custom, which is of British origin, the following deduction is given by Mr Whitaker. "When it was requisite for the Britons to call out their warriors into the field, they used a method that was particularly marked by its expeditiousness and decisiveness, and remains partially among us to this moment. They raised a cry, which was immediately caught by others, and in an instant transmitted from mouth to mouth through all the region. And, as the notice passed along, the warriors snatched their arms, and hurried away to the rendezvous. We have a remarkable description of the fact in Cæsar, and there see the alarm propagated in sixteen or seventeen hours through a hundred and sixty miles in a line. And the same practice has been retained by the Highlanders almost till our own time. When the lord of a clan received intelligence of an enemy's approach, he immediately killed a goat with his own sword, dipped the end of a half-burnt stick in the blood, and then gave it and the notice of the rendezvous to be carried to the next hamlet. This was called the cross-tarric, or fiery cross. It symbolically threatened fire and sword to all his followers that did not instantly repair to the rendezvous. The notice was despatched from hamlet to hamlet with the utmost expedition, and in three or four hours the whole clan was in arms, and assembled at the place appointed. This was the ordinary mode by which the chieftains assembled their followers for war. The first person who received the notice set out with it at full speed, delivered it to the next he met, who instantly set out with the same speed, and handed it to a third. In the rebellion of 1745 it was sent by an unknown hand through the region of Breadalbane; and flying as expeditiously as the Gallic signal in Cæsar, traversed a tract of thirty-two miles in three hours. This quick method of giving a diffusive alarm is even preserved among ourselves to the present day; but is applied, as it seems from Cæsar's account above to have been equally applied among the Celtæ, to the better purposes of civil polity. The *hutesium and clamour* of our laws, and the *hue and cry* of our own times, is a well-known and powerful process for spreading the notice and continuing the pursuit of any fugitive felons. The cry, like the clamour of the Gauls or the summons of the Highlanders, is taken from town to town and from county to county; and a chain of communication is speedily carried from one end of the kingdom to the other."

HUESCA, a city of Spain, in the province of Aragon. It is built at the junction of the two rivers Alcanadre and Isuela, which fall into the Ebro. It is the see of a bishop, and has an episcopal palace, with a very sumptuous cathedral. Within this city is a magnificent university, consisting of two colleges, and both amply endowed. The country around it is highly fertile, and there are manufactories both of linen and woollen. It is a city of very ancient origin, and the walls built by the Romans are still visible around it. It contains 6800 inhabitants.

HUESCAR, a small city of Granada, in Spain. It is near the borders of Murcia, on the banks of the Almanzora. A canal, projected and commenced here formerly, has been suffered to languish, if not to fall into decay. It was designed to irrigate the lands in Lorca, Totana, and other dry parts of Murcia, and to afford water carriage for timber, hemp, flax, and other stores, from the Sierras de Huescar, to the royal arsenal of Carthagena. This city has a castle, and a population of 3000 inhabitants.

HUET, PETER DANIEL, bishop of Avranches, was born at Caen on the 8th of February 1630, and early distinguished for his love of letters and philosophy. His parents having died whilst he was yet an infant, Huet fell into the hands of guardians who neglected him; but his invincible love of learning enabled him to surmount every disadvantage, and he finished his studies in the belles-lettres before he had completed his thirteenth year. He studied philosophy under Father Mambrun, a Jesuit, who, in imitation of Plato, directed him to commence by learning geometry; and Huet contracted such a relish for the mathematics, that he applied himself to almost every branch of the exact sciences, and maintained public theses thereon at Caen. But he was withdrawn from this pursuit by the *Principles* of Descartes on the one hand, and the *Sacred Geography* of Bochart on the other. Of Descartes, then in all his vogue, Huet was a warm admirer, and, for many years, adhered to his philosophy, which, however, he at length saw reason to abandon as visionary. But the work of Bochart, who, like himself, was a native of Caen, made a more lasting impression upon his mind, and inspired him with that taste for erudition by which he was afterwards so much distinguished. In 1652 Huet accompanied Bochart in a visit to Sweden, where he met with a most gracious reception from the queen, Christina. In undertaking this journey he had two objects in view; one was, to see Christina, who was then occupied in regulating and improving her states; and the other to become acquainted with the learned men by whom that princess was surrounded, and to examine the ancient manuscripts in her possession, particularly one of the works of Origen. He returned with literary treasures of more than one kind, which in due time he communicated to the public. Scarcely had he revisited his native city, when, in conjunction with some friends, he formed there an academy for the encouragement of learning, which, we believe, is still in existence. The reputation and merit of Huet, however, had not procured him any solid recompense, when, in 1670, he was united as sub-preceptor with Bossuet, who had just been appointed to superintend the education of the Dauphin. It was at this period that he took occasion to embark in a work which suited him perfectly, and in which he was engaged nearly twenty years. In conformity with a suggestion of the Duke of Montausier, he formed the plan of those editions of the Latin classics, *ad usum Delphini*, destined for the instruction of his illustrious pupil; and it was he who directed the execution of the undertaking. In 1674 he was received into the French Academy; and it may be remarked that, in his inaugural discourse, he complained that ancient learning was then held in little estimation, being almost banished from the commerce of the polite world, and buried in the dust and obscurity of a few cabinets. Fléchier, who was then director of the academy, spoke in reply, and dwelt upon the protracted and useful studies which had been the delight of the Abbé Huet in his early youth, and which formed the sole occupation, as well as passion, of his more mature years. His duties as sub-preceptor did not prevent him from satisfying his ardent taste for the most difficult languages, and the most ancient books. Leaving court in the evening, he occasionally passed entire nights in the libraries of Paris, whence he derived the information which he could not obtain from his own. In 1678 Louis XIV. granted him, as a recompense for his zeal and services, the abbey of Avenay, near Caen, where he composed the greater part of his works. In 1685 he was appointed to the bishopric of Soissons, of which, however, he did not take possession; he had not, in fact, received the bulls in 1689, when M. Brûlart de Sillery, nominated for the bishopric of Avranches, proposed to him an exchange. This latter see was much more acceptable to Huet, because it fixed him at no great distance from his native city and his abbey; but he was not consecrated until 1692, by reason of some differences which had arisen between the court of France and that of Rome. Huet did not neglect his episcopal duties; but when these were discharged, he indulged his love of learning with so much ardour, and passed so much time in his library, that men of the world, and even ecclesiastics, who had business to transact with him, could scarcely obtain access to the studious prelate. An individual who had often been told, when he called, that the bishop could not be seen, because he was occupied among his books, withdrew one day, much dissatisfied; "why," said he, "has the king sent us a bishop who has not yet completed his studies." Huet, however, did not long retain his preferment. Sensible of growing infirmities, and finding that he could not reconcile his tastes with his duties, he resigned his bishopric, and received in exchange the abbey of Fontenay, situated at the gates of Caen. Some time afterwards he repaired to Paris; established himself in the Jesuits' College there, to which he presented his fine library; and, during twenty years, divided his time between prayer and study, for which he preserved his taste to the last. Zealous for the glory of that religion which, in more than one work, he had ably defended, he closed his long and honourable career on the 26th January 1721, at the advanced age of about ninety-one. The works of Huet, the greater part of which continue to be held in high estimation, are, 1. De Interpretatione libri duo, 1°. de optimo genere interpretandi, 2°. de claris interpretibus, Paris, 1661, in 4to; 2. Origenis Commentaria in Sacram Scripturam, Greek and Latin, Rouen, 1668, in two vols. folio; 3. Lettre sur l'origine de Romans, Paris, 1670; 4. Demonstratio Evangelica, Paris, 1679, in folio; 5. Censura Philosophiæ Cartesianæ, Paris, 1689 and 1694; 6. Quæstiones Alnetanæ de Concordia Rationis et Fidei, Caen, 1690; 7. De la situation du Paradis terrestre, Paris, 1691, in 12mo; 8. Nouveaux Mémoires pour servir à l'Histoire du Cartesianisme, 1692, in 16to; 9. Statuts Synodaux, Caen, 1693, in 12mo; 10. Huetii Carmina, Utrecht, 1700, in 12mo; 11. Histoire du Commerce et de la Navigation des Anciens, anonymous, Paris, 1716, in 12mo; 12. Petri Danielis Huetii Commentarius de rebus ad eum pertinentibus, Amsterdam, 1718, in 12mo; 13 Traité Philosophique de la faiblesse de l'Esprit Humain, Amsterdam, 1723, in 8vo; 14. Origines de Caen, Rouen, 1706, in 8vo; 15. Diane de Castro, ou le faux Yncas, 1728, in 12mo; 16. Latin notes on *Manilius*, 1679, in 4to; 17. Dissertations sur diverses matières de Religion et de Philologie, published by the Abbé Tilladet in 1714; 18. Opuscules sur la Langue Française, by the same. (A.)

HUFINGEN, a city, the capital of a bailiwick of the same name, in the duchy of Baden, and circle of the Lake. The bailiwick comprehends four cities or walled towns, twenty-seven villages and hamlets, with a population of 10,950 persons. The city stands on the river Bregach, and contains 201 houses, with 1370 inhabitants, subsisting by agriculture.

HUGUENOTS, an appellation given by way of contempt to the Reformed or Protestant Calvinists of France. The name originated in the year 1560, though authors are not agreed as to the occasion thereof; but the following derivations have been suggested. One of the gates of the city of Tours is called the gate Fourgon, by corruption from *feu Hugon*, the late Hugon. This Hugon was once Count of Tours, according to Eginhard in his life of Charles the Great, and to some other historians. He was it seems a very wicked man, who by his fierce and cruel temper made himself dreaded; so that after his death he was supposed to walk about in the night-time, beating all those he met with. This tradition the learned Thuanus has not scrupled to mention in his history. Davila and other historians pretend that the nickname of *Huguenots* was first given to the French Protestants, because they used to meet in the night-time in subterraneous vaults near this gate of Hugon; and what seems to countenance this opinion is, that they were first called by the name of ulk ll.

Huguenots at this city of Tours. Others assign a more illustrious origin to the name; and say that the Leaguers gave it to the Reformed, because the latter were for keeping the crown upon the head of the line descended from Hugh Capet; whereas the former were for giving it to the house of Guise, as descended from Charles the Great. Others again derive it from a French and faulty pronunciation of the German word *edignossen*, signifying confederates, and originally applied to that valiant part of the city of Geneva which entered into an alliance with the Swiss cantons, in order to maintain their liberties against the tyrannical attempts of Charles III. duke of Savoy. These confederates were called *Eignots*, whence Huguenots.

The persecution which the Huguenots underwent has scarcely any parallel in the history of religion. Though they obtained a peace from Henry III. in 1576, it was only of short continuance; and their sufferings, mitigated by the famous edict of Nantes, granted to them in 1598 by Henry IV. were again renewed, after the revocation of that edict by Louis XIV. in 1685.

HULK, an old ship of war, fitted with an apparatus to fix or take out the masts of ships of the royal navy, as occasion requires.

Hulk is also a name bestowed on any old vessel laid up as unfit for further service. It is probably derived from the ὁλκαδες, or vessels of burthen, of the ancient Grecians.

HULL, a sea-port town of the east riding of the county of York, 234 miles from London by way of York, and 170 by way of Lincoln, and crossing the Humber from Barton. It is situated on a river of the same name, whose waters are received at the town into the Humber. The old part of the town, with the exception of the fine market-place, is ill built, with narrow streets; but that portion near the docks consists of handsome and commodious houses and streets. It is admirably situated for trade, from being at the mouth of the great rivers Humber, Ouse, and Trent, whose tributary streams, and the various canals that branch from them, afford facilities for the conveyance of the productions of a large space of country to Hull, and for receiving from it the requisite articles of foreign growth. These advantages have been improved by the activity of the inhabitants, who have constructed docks and warehouses, which, for accessibility and security, are only inferior to those of London and Liverpool. The building and equipment of ships is an important branch of industry; and those built at Hull are considered as superior to those constructed at the more northern ports. As there is a vast trade with Russia, Prussia, Sweden, and Denmark, centring at Hull, the builders are enabled to procure timber, iron, flax, hemp, and other articles for ship-building, on the most favourable conditions. This is the port from which the greater number of ships are despatched to the whale fishery on the coasts of Greenland. The owners of ships in Hull do not confine themselves to the trade of their own port, but charter them to all parts of the world, by the merchants of London, Liverpool, and other mercantile places. A considerable direct trade is carried on with the West India islands, with South America, the United States, the Mediterranean, and the ports of Holland and Belgium. Though the ancient gates remain, there are no land fortifications; but on the sea side the approach to the town is defended by competent batteries. As Hull is situated in the fertile district of Holderness, it is well supplied with necessaries from that part, as well as from the Lincolnshire country, on the other side of the Humber. It is a county of itself, with its own courts, sheriffs, and assizes; and a branch of the Trinity House has the superintendence of the pilots and the lights. It is governed by a mayor and aldermen, and returns two members to parliament, chosen by the resident freemen and householders, who amount to about 3800. The town was formerly subject to inundations; but, by appropriate embankments and drainage, that inconvenience is no longer felt. The population amounted in 1801 to 29,516, in 1811 to 26,792, in 1821 to 31,425, and in 1831 to 32,958. If to this be added the inhabitants of Drypool, Sutton, and Sulcoates, which form a part of the town, the whole population will be from 45,000 to 50,000.

Hull.

The gradual increase of the foreign trade of Hull may be seen by the following account of the number of vessels which have entered from foreign parts in each year from 1820 to 1833 both inclusive.

Years.	British Vessels.		Foreign Vessels.	
	Ships.	Tonnage.	Ships.	Tonnage.
1820	627	117,434	117	15,111
1821	578	113,133	106	13,820
1822	672	134,999	103	14,011
1823	778	153,313	203	26,103
1824	776	142,615	510	58,603
1825	1,171	227,363	1000	100,773
1826	717	130,674	854	70,137
1827	982	191,364	800	72,338
1828	881	156,925	674	60,082
1829	883	165,791	603	58,854
1830	897	163,657	556	51,015
1831	974	187,361	725	73,547
1832	762	140,788	454	43,481
1833	755	142,301	610	62,403
	11,453	2,167,718	7315	720,278

The amount of duties paid at the custom-house is next in value after London, Liverpool, and Bristol. The sum collected in the year 1833 amounted to L.624,057. 7s. 11d., from which was deducted, for drawbacks, bounties, and over-entry certificates, L.5292. 9s. 3d., and for the payment of salaries and incidents, L.24,470. 4s. 3d.; thus leaving a clear sum of L.594,294. 14s. 3d. remitted to London.

Another criterion of the proportional amount of trade is the amount of postage paid. By this Hull will appear to be the sixth town of England, and the tenth of the united kingdom. The sums collected at the towns at the post-office were,

	1833.	1834.
London	L.632,696	L.642,871
Dublin	80,611	69,096
Liverpool	70,011	74,080

Without more voluminous accounts than the nature of this work will admit, it is not easy to give a tolerable view of the articles imported at and exported from Hull; but an official account, in a condensed form, of the countries from which the vessels arrived that had entered the port of Hull in the years 1830, 1831, 1832, and 1833, will convey a tolerably accurate view of the nature of the whole trade.

Vessels that entered Hull during Four Years.

Hull, in nautical language, is the main body of a ship, without either masts, yards, sails, or rigging. Thus, *to strike a hull* in a storm, is to take in her sails, and to lash the helm on the lee-side of the ship; and *to hull*, or *lie a-hull*, is said of a ship the sails of which are thus taken in, and helm lashed a-lee.

HULST, a city of the Netherlands, in the province of Friesland and circle of Goes. It is strongly fortified, and, by means of a canal, is connected with Helle-Gat, which is joined to the West Scheldt at Ghent. It contains 400 houses, and (in 1830) 2124 inhabitants. Long. 4. 36. 25. E. Lat. 51. 16. 54. N.

HUMAN, in general, is an appellation given to whatever relates to mankind. Thus we say, the human soul, human body, human laws, and the like.

HUMANITY, the peculiar nature of man, by which he is distinguished from all other beings.

Humanities, in the plural, signify grammar, rhetoric, and poetry, known by the name of *literæ humaniores*.

HUME, David, an illustrious philosopher and historian, was born in the south of Scotland, on the 26th of April, old style, in the year 1711. His father was a descendant of the family of the Earl of Home or Hume; and his mother, whose name was Falconer, was descended from that of Lord Halkerton, whose title came by succession to her brother. This double alliance with nobility was a source of great self-complacency to Hume, who was not philosopher enough to despise such distinctions. But being the younger son of a country gentleman of no great fortune, his patrimony was consequently insufficient to support him. For this reason he was destined for the bar, and passed through the usual course of academical study in the University of Edinburgh; but having conceived an early passion for letters, he contracted an insurmountable aversion for any other pursuit; and whilst his friends imagined that he was poring over Voet and Vinnius, he was secretly occupied with Cicero and Virgil. His fortune, however, being small, and his health somewhat affected by close application, he was induced to make a feeble attempt at engaging in business; and in the year 1734, he went to Bristol, with recommendations to some eminent merchants of that city. But the bustle and activity of a mercantile city were by no means suited to his meditative disposition; and, in a few months, he left it in disgust. Immediately after this, he went over to France with the view of prosecuting his studies in private, and established himself first at Rheims, and then at La Fleche in Anjou, where, in order to maintain his independence, he practised the most rigid frugality. The writings of Locke and Berkeley having directed the attention of many learned men towards metaphysics, Mr Hume had early applied himself to studies of this kind, and, during his retreat, composed his Treatise of Human Nature, which he published at London in 1738. This work he had meditated even while at college; a circumstance which proves at once the self-sufficiency of Hume, and the early bias of his mind towards scepticism. He had the mortification, however, to find his book generally neglected, and to perceive that the taste for systematic writing was now upon the decline. "It fell," he says, "dead-born from the press, without reaching such distinction as even to excite a murmur among the zealots." He adds, however, that "being naturally of a cheerful and sanguine temper, he soon recovered the blow." But this pretended equanimity was, we suspect, mere affectation. For the work, so far from passing altogether without notice, was criticised with much ability in the only review of that period, *The Works of the Learned;* and the critique has with some reason been ascribed to Warburton. One remark of the reviewer is singular, and may be almost thought prophetic. "This work abounds with egotisms. The author would scarcely use that form of speech more frequently, if he had written his own memoirs."

In 1742, Mr Hume published, with more success, the first part of his Essays moral, political, and literary. But these, though better received than his former publication, contributed little to his reputation as an author, and still less to his profit; and his small patrimony being now almost spent, he accepted an invitation from the Marquis of Annandale to go and live with him in England. With this nobleman he remained a twelvemonth, during which time his small fortune was considerably increased. He then received an invitation from General St Clair to attend him in the capacity of secretary to the expedition which was at first meant against Canada, but afterwards ended in an incursion on the coast of France. In 1747, he received an invitation from the general to attend him in the same situation in his military embassy to the courts of Vienna and Turin. He then wore the uniform of an officer, and was introduced at these courts as aide-de-camp to the general, along with Sir Harry Erskine, and Captain, afterwards General Grant. These two years were almost the only interruptions which his studies experienced during the whole course of his life; but his appointments made him some compensation on this account, for he was now "master of near L.1000," and, in his own opinion, "independent." In 1749 he returned to Scotland, and lived about two years with his brother at his country-house, where he composed the second part of his essays, called Political Discourses. And now the general approbation of his productions was indicated by a more extensive sale than formerly, and likewise by the numerous answers published by different persons in order to counteract their supposed pernicious tendency. In 1752 were published at Edinburgh his Political Discourses, the only work of his which was well received on its first appearance; and the same year at London, his Inquiry concerning the Principles of Morals, which in his own opinion was incomparably the best of all his works. This year also he was appointed librarian to the Faculty of Advocates at Edinburgh; but the principal advantage resulting from this employment was, that he had thereby the command of a large library. He then formed the design of writing the History of England; but deeming the whole to be too extensive, he confined himself to the history of Britain under the house of Stuart; and in 1754 published the first volume, entitled A Portion of English History, from the Accession of James I. to the Revolution, in 4to. The book, however, was almost universally decried on its first appearance, and soon afterwards seemed to sink into oblivion. Dr Herring, primate of England, and Dr Stone, primate of Ireland, were the only persons of the author's acquaintance who approved of the work, and sent him messages not to be discouraged.

But notwithstanding the approbation of these eminent men, Mr Hume's spirits were so much sunk by his want of success, that he had some thoughts of retiring to France, changing his name, and bidding adieu to his own country for ever. This design, however, was rendered impracticable by the breaking out of the war of 1755 between France and Britain. He then published his Natural History of Religion, to which, soon after its appearance, an answer was published in the name of Dr Hurd, bishop of Lichfield and Coventry, though, in reality, it proceeded from Bishop Warburton, as Dr Hurd afterwards expressly declared. In 1756 was published the second volume of the History of the Stuarts. This was better received, and helped to retrieve the character of the former volume. Three years afterwards his History of the House of Tudor made its appearance, and was almost as ill received as the History of the Stuarts had been, the reign of Elizabeth being particularly obnoxious. The author, however, had now learned to despise popular clamour; and proceeded to finish at his leisure the more early part of the English history, which was published in 1761, and received with tolerable success.

Mr Hume being now turned of fifty, and having obtained by the sale of his books a competent fortune, retired into his native country of Scotland, determined never more to set his foot out of it. From this resolution, however, he was diverted by the Earl of Hertford, whom he attended as secretary in his embassy to Paris in 1763. In 1765, the earl being appointed lord-lieutenant of Ireland, Mr Hume was intrusted with the sole management of the business of the state till the arrival of the Duke of Richmond towards the latter end of the year. In 1767, he returned to Edinburgh, with a much larger income, procured for him by the Earl of Hertford, than he formerly possessed; and now formed the same design he had previously entertained, namely, of burying himself in his philosophical retreat. In this, however, he was again disappointed, by receiving an invitation from General Conway to become under secretary of state; and this invitation he was prevented from declining, both by the character of the person, and his connections with Lord Hertford. In 1769 he returned to Edinburgh, possessed of L.1000 a year, healthy, and, though somewhat stricken in years, yet having a prospect of long enjoying his ease, and of seeing the increase of his reputation. Of his last illness and character he has himself given the following account:—"In spring 1775 I was struck with a disorder in my bowels, which at first gave me no alarm, but has since, as I apprehend it, become mortal and incurable. I now reckon upon a speedy dissolution. I have suffered very little pain from my disorder; and, what is more strange, have, notwithstanding the great decline of my person, never suffered a moment's abatement of my spirits; insomuch that were I to name the period of my life which I should most choose to pass over again, I might be tempted to point to this latter period. I possess the same ardour as ever in study, and the same gaiety in company. I consider, besides, that a man of sixty-five, by dying, cuts off only a few years of infirmities; and though I see many symptoms of my literary reputation breaking out at last with additional lustre, I know that I could have but few years to enjoy it. It is difficult to be more detached from life than I am at present. To conclude, historically, with my own character, I am, or rather was (for that is the style I must now use in speaking of myself, which emboldens me the more to speak my sentiments)—I was, I say, a man of mild dispositions, of command of temper, of an open, social, and cheerful humour, capable of attachment, but little susceptible of enmity, and of great moderation in all my passions. Even my love of literary fame, my ruling passion, never soured my temper, notwithstanding my frequent disappointments. My company was not unacceptable to the young and careless, as well as to the studious and literary; and as I took particular pleasure in the company of modest women, I had no reason to be displeased with the reception I met with from them. In a word, though most men anywise eminent have found reason to complain of calumny, I never was touched, or even attacked, by her baleful tooth; and though I wantonly exposed myself to the rage of both civil and religious factions, they seemed to be disarmed in my behalf of their wonted fury. My friends never had occasion to vindicate any one circumstance of my character and conduct; not but that the zealots, we may well suppose, would have been glad to invent and propagate any story to my disadvantage; but they could never find any which they thought would wear the face of probability. I cannot say there is no vanity in making this funeral oration of myself, but I hope it is not a misplaced one; and this is a matter of fact which is easily cleared and ascertained." His fears concerning the incurableness of his disorder proved too true. He died on the 25th of August 1776, and was interred in the Calton-hill burying-ground, Edinburgh, where a monument is erected to his memory.

Hume's account of his own life is dated only four months previous to his decease; and as he was then aware that a recovery from the malady under which he suffered was hopeless, if not impossible, it may be considered as the testimony of a dying man respecting his own character, conduct, and opinions. But it disappointed those who expected to find in it some acknowledgment of error in speculation, and perhaps also some expressions of regret for the injury done to many by the promulgation of doctrines calculated to unsettle their faith and annihilate their hopes in religion. Hume, however, was not a man from whom any thing of this sort could have reasonably been expected. Devoid of all sense of religion in his own mind, and constitutionally disposed to call in question the received opinions concerning it, he had, from a mere fondness for speculation, mixed with a love of philosophical applause, laboured to extirpate from the human mind all respect for the authority of revelation, or the obligations imposed by it, and had even treated the disciples and advocates of Christianity with a contempt bordering on detestation, "as if he had been revenging a personal injury." Having early imbibed the principles of a philosophy the direct tendency of which was to unsettle all the foundations of belief, philosophical and moral, as well as religious, and thus to undermine the best interests and dissolve the firmest bonds of society, he went on doubting until he even doubted whether he doubted, and at last became so entangled in the inextricable mazes of scepticism, that all kinds of opinion or belief appeared to him involved in nearly equal uncertainty. With a mind thus overclouded by its own speculation, and a natural temper, in which quiet self-love was interwoven with perfect equanimity, it is scarcely to be wondered that Hume, instead of being visited by repentance or regret, should have terminated an otherwise irreproachable life "in such a happy composure of mind that nothing could exceed it." In short, he died in the same state of mind in which he had lived, "believing nothing, and fearing nothing;" and though, to men of different sentiments, there is something sickening in the levity of his imaginary conversations with Charon, when in the near prospect of eternity, yet this seems in no degree inconsistent with our general conception of his character, and still less with the desire of rendering his death a sort of triumph to philosophy, over what he and some at least of his friends deemed superstition. In fact, he was at last surrounded by men who, from congeniality of sentiments, contemplated his end with satisfaction; and it is by no means improbable, that the same love of approbation for which he was distinguished throughout life, should have contributed to give a peculiar colouring to its close. But however this may have been, his social qualities, his wit, his acuteness, his generosity, and, we may add, his fame, preserved to him the regard of his learned countrymen, who forgot the sceptic in the philosopher, and the infidel in the historian.

It is indeed as an historian and a political writer that Hume will perhaps be best known to posterity. Yet even in his capacity of historian he has many faults. As slavish in politics as he was daring in religion, he does not scruple to disguise facts from party motives; and he seldom omits an occasion to sneer at Christianity under the name of fanaticism or superstition. The inexpressible charm of his style has been universally felt and acknowledged; but this is at best only a poor compensation for that negligence which prevents an historian from discovering the truth, or that prejudice which leads him to misrepresent it. Hume, we fear, sinned in both ways; and his reputation has suffered in consequence. His errors have been detected, his misrepresentations exposed, and his unjust aspersions refuted, often by the very authorities which he professed to have consulted. But his political and historical disquisitions display throughout an acuteness, penetration, and comprehensiveness which no writer of modern times has approached, and which, notwithstanding all the defects we have alluded to, will secure to him a rank permanently high in the literature of his country. In his political essays, he anticipated many truths, which it has required more than half a century adequately to unfold and illustrate.

Of the character of Hume as a speculative philosopher the reader will find the most able and exact appreciation in the First and Second Dissertations prefixed to the present work. That he was profound, far-sighted, and even original, in as far at least as originality consists in discovering consequences which had escaped the penetration of others, has been admitted even by his opponents; nor can it be doubted that intellectual philosophy has benefited by the rare sagacity with which he traced some of the prevailing systems to their necessary consequences, and thus showed how dangerous it is to form theories on a subject where the sphere of observation is extremely confined, and direct experiment is in a great measure impracticable.

Few books have been so often reprinted as Hume's History, and none has ever experienced greater injustice, than by being united, in the same form, with Smollett's Continuation. The best and most complete edition of his philosophical works, is that which was published at Edinburgh, 1826, in four vols. 8vo, including all the essays, and exhibiting the more important alterations and corrections in the successive editions published by the author. In this edition, which was superintended by Mr David Constable, the essays are reprinted from that of 1777, corrected by the author for the press a short time before his death, and which he desired to be regarded as containing his philosophical principles; whilst the essays contained in the early editions, but which were omitted in that of 1777, are annexed to the fourth volume, together with two essays, the one on Suicide, and the other on the Immortality of the Soul. In addition to the author's Life, written by himself, the account of his controversy with Rousseau, originally printed in French, and shortly afterwards (in 1766) in English, is also prefixed. The English translation was superintended by Mr Hume himself; and as it relates to an extraordinary occurrence in the lives of these eminent persons, it has justly been thought a suitable appendage to the short memoir which Mr Hume left of his own life.

HUMECTATION, formed of humour, moisture, moistening, in pharmacy, the preparing of a medicine by steeping it for a time in water, in order to soften and moisten it; or to cleanse it, or prevent its subtile parts from being dissipated in grinding, or the like.

Humectation is also used for the application of moistening remedies. In this sense we say, embrocations, emplasters, unctions, humectations, fomentations, and so on.

HUMIDITY, that quality in bodies by which they are capable of wetting other bodies. This differs very much from fluidity, and seems to be merely a relative thing, depending on the congruity of the component particles of the liquor to the pores of such particular bodies as it is capable of adhering to, penetrating a little, or wetting. Thus, for instance, quicksilver is not moist with regard to our hands or clothes, but may be called so in reference to gold, tin, or lead, to whose surfaces it will perfectly adhere, and render them soft and moist.

HUMILIATI, a congregation of religious persons in the church of Rome, established by some Milanese gentlemen upon their release from prison, where they had been confined under the Emperor Conrad, or, as others say, under Frederick I. in the year 1162. This order, which acquired great wealth, and had no less than ninety monasteries, was abolished by Pope Pius V. in 1570, for their luxury and cruelty, and their houses given to the Dominicans and Cordeliers.

HUMILIATION, the act of humbling or of abating a person's pride, and bringing him lower in his opinion. In this sense humiliation is distinguished from mortification; for humiliation brings down the mind, but mortification subdues the flesh.

HUMILITY is a virtue consisting in the moderate value which a person puts upon himself, and every thing relating to him. Or, more particularly, it consists in not attributing to ourselves any excellence or good which we have not; in not overrating any thing which we have or do; in not taking an immoderate delight in one's self; in not assuming more of the praise of a quality or action than belongs to us; and in a lowly sense and acknowledgment of our imperfections, errors, and sins. This virtue expresses itself in the modesty of our appearance, of our pursuits, and of our behaviour towards other men. It is distinguished from affectation, bashfulness, and meanness.

HUMMOCK Island. There are two small islands of this name, in the Eastern Seas, one fifteen miles south of Mindanao, in long. 126. 37. E. and lat. 5. 24. N. The other, which is inaccessible except at one point, lies in long. 123. 40. E. and lat. 24. 15. N.

HUMOUR, from the Latin *humor*, in its original signification, stands for moisture in general; and hence it has been restricted to signify the moisture of animal bodies, or those fluids which circulate through them. As the temper of the mind has been supposed to depend upon the state of the fluids in the body, humour came to be synonymous with temper and disposition.

Humour is often made use of to express a particular species or modification of wit. See Wit.

HUMPHREY, Laurence, a learned English divine, was born at Newport-Pagnell, Buckinghamshire, about the year 1527. He received his school education at Cambridge, and afterwards became a fellow of Magdalen College, Oxford, where he took his degree as master of arts in 1552. In 1555 he retired, with other Protestant refugees, to Zurich, in Switzerland, where he resided for some time; but after the death of Queen Mary he returned to England, where he was restored to his fellowship in Magdalen College, from which he had been expelled, and, in 1560, appointed queen's professor of divinity at Oxford. In 1570 he was made dean of Gloucester; in 1580 he was removed to the deanery of Winchester; and, if he had not been disaffected towards the church of England, in other words, a moderate and conscientious nonconformist, he would probably have been raised to the episcopal bench. Humphrey was considered as a great and general scholar, an able linguist, a profound theologian, and, for his time, an excellent writer. He died early in 1590, leaving a wife who had brought him twelve children. His works are, 1. Epistola de Græcis literis, et Homeri lectione et imitatione, Basil, 1558; 2. De Religionis conservatione et reformatione, deque primatu Regum, Basil, 1559; 3. De Ratione interpretandi auctores, Basil, 1559; 4. Optimates, sive de Nobilitate, ejusque antiqua origine, Basil, 1560; 5. Joannis Juelli Angli, Episcopi Sarisburiensis, Vita et Mors, London, 1573; 6. Two Latin Orations spoken before Queen Elizabeth, one in 1572, and the other in 1575; 7. Sermons; 8. Some Latin pieces against the Papists, particularly Campian. (A.)

Hundred || Hungary.

HUNDRED, Hundredum, or *Centuria*, a part or division of a county, and anciently so called from its containing an hundred families, or from its furnishing an hundred able men for the king's wars. After Alfred's dividing England into counties, and giving the government of each county to a sheriff, these counties were divided into hundreds, of which the constable was the chief officer.

HUNFELD, a town of the province of Fulda, in Hesse-Cassel, the capital of a bailiwick of the same name, which contains one town and thirty-two villages, with 7633 inhabitants. The town is situated on the river Haun, and has some considerable bleacheries, with 1730 inhabitants.

HUNGARY.

This is the largest division of the dominions under the government of the imperial house of Austria. It is formed into three separate parts, politically distinguished as the kingdom of Hungary, the principality of Siebenburgen, and the military districts of Carlstadt, Warasdin, and the Bannat. Although the other parts will be noticed in their alphabetical order in this work, this general head will comprehend such circumstances as may be applicable to the whole, because its chief purpose is to describe what, in the Austrian administration, is denominated the kingdom of Hungary.

The names of the circles, their extent, their population, and the capitals of each circle, are as follow:

Circles.	Extent in Square Miles.	Population.	Capital Cities.
Hither Danube......	21,890	2,572,129	Presburg.
Farther Danube......	17,402	1,943,143	Ungrisch-Altenburg.
Hither Theissa......	15,249	1,597,105	Leutschau or Locse.
Farther Theissa.....	27,368	2,231,353	Szigeth.
Sclavonia..............	3,784	348,340	Eszek or Essegg.
Croatia................	3,786	558,066	Warasdin.
Peculiar (*besondere*) Districts............	15,718	1,121,136	Agram or Zagrab.
	105,197	10,371,272	

The capital of the whole kingdom was formerly the city of Presburg, but since 1784 that honour has been enjoyed by the city called by the Germans Ofen, and by the Hungarians Buda, which is in fact a kind of suburb to the city of Pesth, but separated from it by the river Danube, over which there is a long wooden bridge, which keeps up the communication between the two places, whose united population amounts to 95,000 souls.

Races of the people.

Few countries contain a greater variety of races than are to be found in the population of Hungary, or classes varying more in their language, religion, occupations, manners, and in their progress towards civilization. The most numerous of these races are the *Magyars*, the original inhabitants. They reside chiefly in the central and most fruitful plains, where the agriculture is most easily conducted, and leave to the Sclavonians that part of the country which is mountainous or sterile, or where more severe labour is required. They are remarkable for their strength rather than their height, being very muscular, with broad shoulders, but with rather short legs and arms; and their countenances are distinguished by a conscious expression and a look of self-importance. Their language is clear and concise, and the sound of it is soft and pleasing. They are much attached to it, and generally prefer it to the Latin, which all but the very lowest of them can speak. They are divided into three branches, each of which has its peculiar dialect, and are distinguished by the districts they occupy thus: the Magyars of the Danube, the Magyars of the Theissa, and the Paloczin Magyars. Another of the greater races of the people is the Sclavonian, who inhabit chiefly the mountainous districts within the kingdom, both in the north and the south. They are of a darker complexion than the Magyars, but are well formed, and the females are distinguished by their forms, and graceful figures and movements. This race is distinguished by different names, and they differ much in their several dialects. The Slowaks are the oldest settlers in the hilly district, and amongst them are some originally from Bohemia, some few from Poland, many from Red Russia (called Russniaks), and others in the south from Illyria, sometimes called Serbians. In these are comprehended the greater number of the Croatians, many of the Bulgarians, and, near the sea coast, about Fiume, the Liburini. As these have various dialects, some approaching nearer to the Latin than others, but all in some degree connected with that language, the intercourse between the tribes is maintained by a species, much adulterated, of the tongue of ancient Rome. The Germans in Hungary are a numerous body; and the two descriptions of them are distinguished by the natives as Saxons and Suabians. The first settled in the country some centuries ago, and came as colonists from Saxony and the banks of the Rhine. The second colonists have obtained settlements at various but more recent times. The whole number of this race is estimated at about 700,000. They inhabit a tolerably good and extensive breadth of land along the frontiers of the provinces of Austria and Steyermark, from the Danube to the Raab, and have, in the interior of the land, several cities and towns, as well as numerous small places in the southern and western divisions of Hungary. They mostly retain their original language, which, however, is much corrupted by the adoption of words and phrases from the several tribes with which they are in contact. The smaller settlers in Hungary are the Wallachians, the New Greeks or Macedonians, a colony of French in the county of Torontal, another of Italians on the sea-coasts, and numerous Turkish individuals in all the commercial towns and cities. About 140,000 Jews are established in Hungary, who, with some scattered Armenians in most of the towns, form the retail traders.

Classes of inhabitants.

The inhabitants are divided into nobles, citizens, and peasants. The first class, though differing in titles and rank, have all equal privileges; the principal distinction between them is, that, in the assembly of the states, or diet, the magnates have personally a seat and vote; whilst the other nobles vote by their representatives. The higher clergy are considered as nobles, and enjoy similar privileges. The nobility can alone possess free lands, or those enjoying the *jus dominicale*, and they are exempt from taxes, tithes, and the quartering of soldiers; but, on the other hand, they are bound to perform personal military service, when the pressure of circumstances compels the diet to decree the levy *en masse*, or, as it is called, the *insurrection*.

The citizens or burghers are the inhabitants of those cities which own no superior lord but the monarch. These have privileges similar to the nobility, by which they are exempted from the payment of taxes and tithes, and from the quarterings of the military; and their deputies have seats in the diet. They are governed by their own magistrates, and manage their own local funds. They cannot, however, hold estates out of their cities, nor institute a suit against the nobles in their individual names, but only in that of the corporation to which they belong. The peasants generally are slaves, but with a more or less mitigated degree of servitude; and some few, under the denomination of German, or other colonists, are free. The lot of the common peasants has, however, been of late years much improved. They are more protected against the power of their lords, by being allowed to acquire property, and by being permitted to leave their estates to their heirs, and to become, if they can do so, burghers of the royal cities. Their condition is, however, still a severe one, as they bear almost all the burdens of the state, and are incapable of commencing suits in the courts against either the nobility or burghers.

Religio and edu tion.

Although all the Christian sects enjoy equal civil rights and similar legal establishments, the Roman Catholics are the most numerous body. They consist of two classes, one adopting the Latin ritual, the other adhering to that of the Greek church, and called United Greeks. According to a survey made in 1825, the former amounted to 5,233,952 individuals, and the latter to 624,259. The hierarchy for these 5,858,211 persons consists of three archbishops, in the cities of Gran, Kolocsa, and Erlau; of seventeen bishops, viz. in Agram, Bosnie with Sirmien, Esanad, Fünfkirchen, Grosswardein, Kaschau, Neusol, Neitra, Raab, Roseneau, Steinamanger, Stuhlweisenburg, Szathmar, Veszprim, Waizen, and Zeug with Zips; and, besides these, there are the following dignities, viz. 307 canonries, 160 abbeys, eighty-nine archdeaconries, and 307 vice-archdeaconries. This sect has 3723 parochial churches and numerous chapels, which are served by 6345 priests. Next in number to the Roman Catholic is the orthodox Greek or non-united church, comprising 1,452,516 persons. This church has for its rulers an archbishop at Carlovitz, and seven bishops at the cities of Bacs, Temeswar, Carlstadt, Packracz, Arad, Ofen, and Werschetz. They have sixty presbyteries, twenty-five large convents, 1643 churches, 2122 pastors, and 2781 lay ecclesiastics, who form a kind of monks. The Protestant Reformed church, on the Geneva model, consists almost wholly of Magyars, and amounts to 1,251,226 persons. They are under four superintendencies, established in the cities of Pesth, Papa, Miskolcz, and Debreczin; and under these there are thirty-four synods, 1359 churches, and 1407 pastors. The Lutheran church consists of 667,945 members, and is governed by four superintendents or bishops, residing in the cities of Presburg, Neusol, Odenburg, and Teissholz; under these are thirty-five consistories, with 487 parish churches, many chapels, and 518 ministers. Besides these there are a few assemblies of Armenians, and a few Mahommedans. The Jews have 342 synagogues, and a rabbi to each. Though the population has vastly increased since 1825, it is not supposed that the proportional numbers of the several religious parties has been materially altered. Each of these sects has its separate schools, colleges, and universities; and education is more diffused than in many of the other parts of Europe. In most of the sees schools for Catholics are supported by the prelates; and besides, there are royal academies at Agram, Grosswardein, Kaschau, Presburg, and Raab; and at Pesth there is one of the oldest and richest universities in Europe. In the schools of the higher class, including the university, the number of students is stated at 20,318. The schools for primary instruction in the villages are but slightly encouraged, nor do the peasantry discover much inclination for instruction; but in the cities and large towns there are 103 schools for the use of the Catholics. The Protestants of the reformed class, as well as the Lutherans, have schools for primary instruction in each of their parishes. The former have burgher schools in the cities, and seven gymnasiums, and three colleges at Debreczin, Saros-Patak, and Papa, with 4180 students. The Lutherans have nine gymnasiums and good colleges at Eperies, Presburg, Odenburg, and Kesmark, in which there are 2660 students. The non-united Greeks have till recently much neglected the education of the adherents of their church; but of late years some attempts at improvement have been made. They have established some schools, the best of which are at St Andrew, Alt-Ofen, and Miskolcz. As aids to the higher branches of science, may be noticed the astronomical observatories at Ofen and at Elau, the chemical and mineralogical institutes at Schemnitz, the military academy at Pesth, and the society founded in 1832 in that city, under the title of the Imperial Academy of Sciences.

ntains face of coun-

The northern and western sides of Hungary are remarkably mountainous. The Carpathian Mountains form a semicircle extending from the south-east portion of the kingdom till it meets the Danube on the western frontier. In the circle they describe, many projecting ranges extend themselves into the level land. On the western side the Carinthian Mountains cover a considerable portion of the kingdom. The highest points of the Carpathian Mountains are, the Lomnitzer Spitze, 8545 feet above the level of the sea; the great Krywan, 8218; the Caesmark, 8194; and the Uniacke, 7597. The loftiest parts of the Carinthian Mountains, though within the Austrian dominions, form no portion of the kingdom of Hungary, nor do any part of the Noric or Rhætian Alps. The greatest extent of level land in Hungary is found to the eastward of the river Theissa, forming a rich plain of more than 20,000 square miles. Another level, called the Three-Cornered Plain, is found to the eastward of the Danube, beginning near Presburg, the base of which line extends 150 miles in length. The soil is as various as the elevation of the land; on the mountains it is dry and sterile; on the terraces that surround them, of moderate fertility, and of most luxuriant richness on the plains, but mixed with considerable tracts nearly barren, where, for many miles, neither tree, stone, bush, nor living creature, are to be seen, with sand-hills, varying their position with the violent storms that frequently occur.

tiva-

Hungary, however, is a country highly productive, yielding the largest proportion of the necessaries of life of any part of the ancient Austrian dominions, and furnishing, from its surplus, large quantities of corn, tobacco, fruit, wine, and cattle, to the neighbouring states. According to the account of Grellman, the extent of land is 39,329,000 jochs, the joch being equal to an English acre and two fifths. Of this land only 23,905,126 jochs are in cultivation; the remainder is composed of sandy deserts, lakes, morasses, and barren mountains. The productive lands are thus divided: 4,897,218 arable, 638,767 gardens, 911,176 vineyards, 2,129,225 meadows, 5,536,000 pastures, 850,000 ponds, and 8,940,740 woods. The northern part of Hungary scarcely produces sufficient corn for its own consumption; but the south is the granary, not only for the northern part of the kingdom, but, after deficient harvests, for a great portion both of Germany and Italy. The corn consists of wheat, rye, barley, oats, peas, and, in the most southern parts, of rice and maize. Next to the cultivation of corn, the growth of wine is the most considerable object of attention, and managed with the greatest care. The wines of Tokay have long been celebrated throughout Europe, and are of the first class of sweet wines; but the wines of Odenburg, of Rust, and of Ofen, are very highly valued, though but little known beyond the boundaries of the Austrian empire. The whole of the annual produce of wine is estimated by Blumenbach at 4,500,000 hogsheads, and valued at nearly ten millions sterling. Notwithstanding the proportion of woodland, the eastern part of the kingdom is much distressed from the want of fuel; but the west furnishes much wood, both for firing and building, and considerable quantities of gall-nuts, turpentine, pitch, tar, and pot and pearl ashes, for the supply of the surrounding countries. The other productions of agriculture which furnish commerce, are hemp, flax, and tobacco. This last article has been long and successfully cultivated; and that produced in the provinces of Tolna, of Fünfkirchen, and in the peninsula of Murakoz, is highly prized for its peculiarly aromatic flavour. The forests are of great extent, covering nearly 15,000,000 English acres. They furnish abundant fuel for home consumption; and some timber, with much charcoal, is exported. Vast quantities of gall-nuts are collected in the woods; and the bark, especially of the oak, is an article of considerable traffic with Turkey, and with other countries.

Cattle.

The breeding of cattle is an important branch of the rural economy of Hungary. The horses, though small, are active and hardy; but, in spite of the measures pursued by the government to improve the races, they are still much inferior to those of most parts of the empire. They are generally set to work at too early a period, and their food is usually scanty and bad. They have, however, been somewhat improved of late years by the institution of studs in different parts, whence stallions are gratuitously supplied. The whole number of horses does not exceed 480,000 of all kinds. The horned cattle are a race much valued in every part of the empire, though they receive but little attention. The extensive *steppes* between Debreczin, Temeswar, Neusatz, and Pesth, are the native homes of these beasts. Their number is 886,900 oxen, and 1,508,100 cows. These, by their sale to the surrounding countries, produce annually nearly L.500,000 sterling. The numbers of the sheep are stated to be upwards of 8,000,000. There are prodigious flocks on the plains between the Danube and the Theissa, and on the elevated grounds of that district. The wool is coarse, and the owners estimate the cheese, milk, and flesh, more than the fleeces. In Western Hungary, on the other hand, the large flocks having been much improved of late years by crosses with the Merino breeds, and with the sheep of Padua, yield fine wool, which, to the value of L.500,000, is exported. Swine are reared in abundance; and though, when cured, they form the principal animal food of the inhabitants, there are yearly from 200,000 to 250,000 of these animals exported. The feathered tribes furnish a part of the annual wealth of the country. The greater part of the goose feathers, in which the Jews of Prague trade, come from Hungary; and the capital of the Austrian dominions is supplied from thence with that commodity. The rearing of silk-worms has been of late much attended to in some of the southern parts of Hungary, especially in the Bannat. The mulberry trees are very flourishing, and great progress is expected in future, but the undertaking is yet in its infancy.

Minerals.

The southern part of Hungary is a country enriched by minerals of various kinds. About two thirds of the mines belong to the crown, and are worked on account of the government, under an expensive system of administration, and with a profusion of royal officers. These are formed into four divisions, the principal seats of which are at Chemnitz, Schmolnitz, Nagybanja, and Oravicza, and employ, in the various operations, about 45,000 workmen. The labourers occupied in these mining operations are generally emigrants from Moldavia and Wallachia. We have no statistical accounts of the actual produce of the mines; but that of gold, silver, and iron has of late years increased. The first two of these metals have advanced, in the last fifteen years, from the value of L.220,000 to nearly L.400,000, and the increase in iron has been in nearly the same proportion.

Manufactures.

The manufactures of Hungary are yet in an infant state. The kingdom has been long accustomed to supply raw materials to the surrounding countries, and to draw from them their manufactured goods. The inhabitants are not disposed to labour in confined houses; and, till within the last twenty years, their principal occupation, exclusively of agriculture, was confined to making very coarse cloths, and various kinds of woodware, for furniture, musical instruments, and toys. The spinning of flax is a domestic manufactory, carried on by the females of almost every peasant's family. The annual quantity produced is estimated at sixteen million of ells, or about ten million yards, the far greater part of which is consumed within the kingdom. The principal bleaching works are at Roseneau, where about 300,000 ells are annually whitened, all of the finer kind. There is much woollen cloth made in small manufactories scattered over the kingdom, but it is of a coarse quality, and adapted only for the use of the peasantry. Within the last thirty years more extensive factories have been established in Gacs, Illawa, Kaschau, Munkatsch, Lipersdorf, Mosztenie, and Presburg. These have been mostly founded by Germans, and the greater part of the operative people are of that nation. At these places the use of various kinds of machinery has been introduced, and the cloth made in them, from the wool of a mixed breed of sheep, partly of the Merino and partly of the Paduan races, is of fine quality and well finished. There are forty paper-mills in Hungary, which produce printing and writing paper, all of a very wretched quality, except some from the mill belonging to the university, which is tolerably good. Silks and ribbons are made at Pesth, Grosswardein, and Presburg, but to a very small extent. The leather of Hungary is much valued throughout the whole Austrian territories, but the quantity of curried leather, prepared mostly at Presburg, is not equal to the consumption; and the hides of their cattle are sent to Germany, from which they return in a state fit for use. The tanneries are numerous in Presburg, Fünfkirchen, Ratko, Zips, and Debreczin. The iron produced by the native mines is manufactured into the various articles which the wants of the inhabitants require, at Zips, Abouigvar, Sarosch, Zemplin, Vorschod, and through the whole county of Gomorer. The best steel is made in Diosgyvor, and the vicinity of Neusol; and the swords and other weapons manufactured in the different hardware districts are esteemed as of excellent quality, though of clumsy and grotesque forms. Glass is made (but scarcely any but green) in twenty-five glass-houses in different parts of the kingdom. The sugar refiners supply the domestic consumption. Snuff and tobacco are made almost exclusively from the plants raised on their own soil. The soap of Hungary, which is very good, is principally made from natron in Debreczin, where there are seventy-eight manufactories of that article. Linseed-oil, oil of turpentine, corn spirits, cordials, especially Rosoglio, and a medicine for wounds, known through Germany by the name of the Hungarian Balsam, refined saltpetre, and pearl ashes, are the productions of the other manufactories.

Commerce. Hungary is surrounded on every side by the other Austrian dominions. The states of that country are proud of their independence as a separate kingdom, and tenacious of their privileges, especially of their exemption from the taxes imposed by the cabinet of Vienna. As the emperor's government has no wish to embroil itself with the states by attempting internal taxation, it extracts a revenue by surrounding Hungary with custom-houses, where tolls are collected on every commodity that enters into the kingdom, or passes from it into the hereditary states. The toll thus collected is one-thirtieth part of the commodity, or three and a third per cent. on the value of it. The very high rate of carriage, arising from the bad state of the roads, is, however, a greater impediment to the exchange of commodities than even this tax at the frontiers. The principal trade of Hungary beyond the immediate boundaries is with Poland and Silesia, which countries draw from thence their wine, and with the north of Italy, to which its surplus corn is transported. The port of Fiume is connected with Hungary by the only good roads the kingdom possesses, and may be considered as its haven for exportation and importation, and as alone bringing it into contact with distant countries. The central point of internal trade is Pesth, where, at four great fairs, the concourse of buyers and sellers is so great, that the prices settled by them, if they do not absolutely govern, in a great degree regulate, those of the other parts of the kingdom. From the central city the commerce diverges in four great branches: 1*st*, Towards the German Austrian dominions by Raab, Presburg, Komorn, and Odenburg, at each of which places considerable business is transacted; 2*d*, towards Gallicia, through Kaschau, Eperies, and Leutschau; 3*d*, to Siebenburgen, Moldavia, and Wallachia, through Debreczin, Ezegedin, and Temeswar; and, 4*th*, to the Turkish dominions beyond the Danube, through Neusatz and Semlin. At all these places considerable annual fairs or markets are held, which are resorted to by vast numbers of merchants, not only from Germany and Poland, but by the Turks, Armenians, Greeks, and even Tartars. Besides the marts at these cities, there are in Hungary sixteen hundred other places where annual fairs are held. The means of internal transit furnished by the rivers are a great assistance to commerce. The Danube is navigable for craft of two hundred tons burden, the Theissa for those of one hundred; and the other rivers, the Save, the Drave, the Waag, the Gran, the Unna, and the Kulpa, are all navigable for smaller vessels of various dimensions. The recent introduction of steam navigation has been extended to Hungary, and promises great advantages to the future commerce with the Black Sea. Some impediments on the Danube have already been removed, and measures are in progress for removing the remainder; but already several steam-vessels have completed their voyage from Pesth to Constantinople. The chief commodities exported from Hungary are the raw products of the soil. The greatest in amount are live cattle; the next in value to these are, corn, tobacco, wine, hides, and wool. The chief imports are, colonial ware, linen, cotton, and woollen articles for clothing, and some few foreign luxuries. The value of the exports is said to exceed that of the imports to the amount of L.750,000 annually.

Constitution. The government of Hungary is a limited monarchy, at present hereditary in the house of Hapsburg; but, in case of the failure of all the branches of that family, the king, or rather dynasty, becomes elective by the assembled states or diet. The laws by which the constitution was founded, and by which it is maintained, are the *Golden Bull* of their king Andreas II., dated in 1222, the magna charta of the nobles, whose privileges are principally regarded; and these have been confirmed by the peace of Vienna in 1606, and of Lintz in 1647. By these two treaties also the free exercise of their religion is secured to the Protestant sectaries. All these interests were further confirmed by the diet of Presburg in 1687, and by the inauguration diploma of Leopold II. in 1790. These various charters and acts of the states have merely secured to the privileged orders their ancient rights, but have left the peasantry, or, in other words, the great mass of the population, in the same state of subjection as before their promulgation.

The kin The whole executive power is vested in the monarch. He is the source of all titles and offices, and nominates to the higher ecclesiastical dignities, and to the benches of justice. He makes war and peace, can call together and dissolve the diet, and draw forth the whole military population. He receives the incomes of all vacant ecclesiastical benefices, and is heir to the property of such noble families as become extinct. The direction of the universities and colleges belongs to the king, but to the higher offices in them he can only appoint those who are of noble birth. The appeals to Rome upon the affairs of the Catholic church can only be made through him, and the royal authority has been constantly exercised to contract the number and to limit the causes of such applications. The king must be of the Catholic religion, and, at his inauguration, must swear to maintain the privileges and rights of the states. Notwithstanding this oath, by various circumstances, many arising out of the late long wars, the power and influence of the crown have been recently very much extended. Within six months after succeeding to the throne, the king must call together the states, and in their presence, in the open air, swear to maintain the privileges of the states, to leave the crown of St Stephen within the kingdom, and to allow the states to elect a king, upon failure of issue both male and female of the Emperor Charles VI. Joseph I. and Leopold I. During a minority, the palatine is guardian of the king and kingdom; but the monarch is capable of assuming the exercise of power when he has completed his fourteenth year.

St s.

The states of Hungary (*status et ordines*) consist of, 1*st*, the prelates, to which class belong the archbishops, bishops, abbots, and priors of the Greek and Catholic churches; 2*d*, the temporal barons and magnates, the high bailiffs of the provinces, and the counts and independent noble proprietors of estates; 3*d*, the nobility or knights, who do not attend personally, but choose two deputies for each county (*komitat*) or province; and, 4*th*, the deputies from the royal cities. These members are said to be the representatives of Hungary, whilst the mass of the inhabitants, described in their law as *misera plebs contribuens*, have no connection with public affairs, except by paying taxes and furnishing recruits, from both which services the nobles and clergy are exempt. The purposes for which the states assemble are, the coronation of the king, the election of a palatine, the admission to or exclusion of nobles and cities from their rank, the granting subsidies and imposing taxes, and the framing new laws, or rather giving the assent of the assembly to such laws as the king may enact. By the constitution, the states should be convened every five years, or whenever any pressing circumstances require their assembling. Of these circumstances the king must judge, as the states are only convened by his summons. They meet in two chambers, or, as they are denominated, tables. The magnates' table is composed of the royal barons, the high hereditary officers of the kingdom, and the prelates, counts, and free landlords. The other chamber, called the states' table, consists of the deputies of the *komitats*, or the supleans of the nobles, the representatives of the royal free cities, and the persons appointed by such magnates as do not attend, who are called *ablegati absentium*. Though the states meet but in two chambers, yet they vote in four distinct bodies, and the absolute majority of those present determine each question in that body. If the king and three of these bodies determine any point, it becomes a law; and the fourth body has no suspending power. The king appears personally, or by his commissioner, and claims his prerogatives, and the states demand a confirmation of their rights. At the diet in 1792 there were present thirty bishops and other ecclesiastics, 178 counts, 131 hereditary officers and barons, sixteen law officers, thirty deputies of chapters, ninety-eight representatives of *komitats*, 115 supleans of absent magnates, and eighty-two deputies of cities. The sitting of the diet depends on the king, who has usually dismissed them as speedily as possible, out of regard to the general welfare of the people. During the meeting of the diet, all the courts of justice are shut up, and the deputies of the free cities and of the *komitats* are maintained at the time of the session at the expense of the people who send them, whilst the hereditary officers are kept by the crown. From these regulations, it is not to be wondered at that no anxiety for the meeting of the diet is manifested by any part of the kingdom. The king is well aware that no considerable sum beyond what is necessary for the expenses of the local government will often be granted by the diet; and when it is granted, as the whole is squeezed from the hard earnings of the peasants, it is collected with difficulty, and produces great oppression. As each *komitat* has its own provincial diet, in which its affairs are discussed and regulated, and to which appeals from the courts of justice of the nobles (*herren stuhls*) can be made, there is less occasion for the assembling of the general diet; and though, by the constitution, that body should meet every five years, yet, by a general acquiescence, its periodical convocation has been of late dispensed with. Whenever the diet is convoked, the summons of the monarch states the purposes for which they are to meet, in the orders to these subordinate diets; and no other proposition is or can be produced at the assembly. The local diets thus have an opportunity of discussing the propositions that are to be made to the general assembly, of determining what part to take, and of instructing their deputies in what manner to vote. No project of a new law originates with any of the states; and the sittings, though they were formerly very stormy, have of late been rather in compliance with ancient forms, and for purposes of display, than for any objects of great utility.

Great officers.

The principal officer of the kingdom is the palatine, who is the representative of the king, president of the diet, and of the supreme court of justice, dispenser of pardons, and mediator between the monarch and the states; his office continues only one year, but he may be re-appointed. Next to him is the judge of the supreme court, who is the president of the other two, and fills the office of palatine in the absence of that chief. The ban of the Croats follows next in rank, but has no official duties, unless at the coronation, when he carries the golden ball. The hereditary treasurer (*tavernicus*) has a seat in the supreme council, and is captain of the noble Hungarian body guards, who perform the palace duty.

Chancery court.

The administration is conducted by the emperor, through the means of the Hungarian court of chancery in Vienna, which is constituted of twenty-four state councillors, viz. three ecclesiastics, eleven magnates, and ten of knightly rank, all nominated by the monarch. This college exercises the superintendence over churches, schools, and charitable establishments, administers the funds of the universities and convents, and regulates the agriculture, the trade, and the feudal claims. This body has no original jurisdiction in matters of finance or of justice, but may be appealed to by the provincial diets or the local courts of law.

Oppressed state of the people.

The primary courts of law are under the control of the nobles, who appoint the judges and direct the procedure. The oppression in such courts towards those not noble has long been excessive, and, though somewhat mitigated since the reign of Maria Theresa, bears still the deep impression of the worst periods of the feudal government. The whole system of law seems calculated only to secure and perpetuate to the nobility the enormous power they possess. The nobles are exempt from all taxes and imposts of every kind; the only duty they owe to the state is that of personal service in war. If a person not noble assaults one who is so, the legal punishment is death, which is, however, now usually commuted into the forfeiture of all his property, with the privilege of reclaiming it whenever he shall have the means of paying for it a stipulated portion of the value. If a peasant is injured by a noble to whose estate he is attached, he can have no redress, since he can only sue for it in the name and through the medium of the very person against whom he seeks it. The court in which his complaint is to be heard, not only consists of persons who are generally the dependents of the presumed offender, but moreover they can only be assembled at his summons. If a peasant is injured by any other noble, he cannot seek redress in his own person, but only through the intervention of him on whose estate he lives; and such is the contempt in which the peasantry are held, that even this privilege must very often be nugatory. The law of entail is another injurious privilege of the nobility, common, indeed, to all the feudal countries, which puts it out of their power to alienate the estates to the detriment of the successors. The effect of this is, that the possessions of the nobles are of enormous extent, embracing often whole *komitats;* and they are held upon tenures which convert them into the nature of principalities. The kingdom indeed partakes more of the nature of a great military confederation of subordinate chiefs, under one hereditary leader, than of any other known form of government. As all the descendants of noble families are themselves noble, whilst property remains almost unalienable, the poverty into which individuals belonging to distant branches of these families fall is in proportion to their number. In Hungary it is estimated that one person in twenty is of noble birth, all possessing the obnoxious privileges here noticed; many of them, though free from all taxes, sunk to a state of most abject poverty, and some of them filling the offices of peasants or servants. The inhabitants of the free cities are supposed to be about equal in numbers to the nobility; and the remainder of the people, according to these estimates, amounting to eighteen out of every twenty, can have no protection from the laws, nor any resource when injured or oppressed by their superiors. "The noble," says Dr Bright, "pays no tribute, and goes freely through the country, subject to neither tolls nor duties; but the peasant is subject to pay tribute; and although there may be some nominal restrictions to the services due from him to the government, it can safely be said that there is no limit in point of fact to the services which he is compelled to perform. Whatever public work is to be executed, not only when a road is to be prepared, but when new roads are to be made, or bridges built, the county meeting gives the order, and the peasant dares not refuse to execute it. All soldiers passing through the country are quartered exclusively upon the peasantry. They must provide them, without recompense, with bread, and furnish their horses with corn; and, whenever called upon, by an order termed a *forespan order*, they must provide the person bringing it with horses and means of conveyance. Such an order is always employed by the officers of government; and whoever can in any way plead public business as the cause of his journey, takes care to provide himself with it. In all levies of soldiers, the whole falls upon the peasant, and the choice is left to the arbitrary discretion of the lord and his servants."

From the same intelligent traveller we learn, what, indeed, the observations of all ages have taught, that whilst the nobles are hospitable, high spirited, well informed, and zealous to promote such institutions and projects as they think calculated to benefit their country, the peasantry are not only poor, but idle, dissolute, and dishonest. Perhaps in no other country of Europe is highway robbery so frequent; and, as a remarkable trait in the character both of the noble and the peasant, we are told that to every nobleman's house a prison is attached, in which are to be constantly found from ten to twenty miserable wretches, pinioned in a way which would not be tolerated in England towards the worst felons. The dungeons in which they are immured are far more dismal and wretched than any prison in London can exhibit. The extreme viciousness of the Hungarian peasantry seems to have extinguished all feeling in the breasts of the higher nobles for their degraded state; and, instead of the wise policy which, by meliorating their condition, would improve their morals, they are left to endure those punishments which a different state of society would be likely to render unnecessary.

Militar force, a finance.

The military force and the financial affairs of this kingdom are so mixed up with those of the general administration, of the extensive expenditure of which they form a part, that it would be both difficult and tiresome to enter into the representation of them; and, besides, they vary so much from political events at different periods, that what would be correct at one time, would be defective at others.

Langua and lite ture.

Though Hungary has a national language, yet it is not generally spoken, nor supposed to be understood, by more than one third of the inhabitants. The only written language, until within a very late period, was the Latin, in which all their laws and public proceedings were promulgated; and it is still the most common medium of communication. It was not till the reign of Maria Theresa that any experiments were made to improve and polish the national language. When she formed her Hungarian guards, a number of young men of noble families were drawn to Vienna, where they had means of knowing the estimation in which the cultivation of learning was held in the more civilized parts of Europe, and were taught to feel the inferiority of their native country, in not possessing a national language and national literature. This stimulated them to exertions to remove the stigma, and gave birth to most of those writings of which the Hungarians boast. The cultivation of the vernacular tongue was further promoted by the attempt of the Emperor Joseph to introduce the German tongue into their public transactions; this roused the patriotic spirit of the Hungarians, and the effect of that spirit became visible in the extension and improvement of the native language. Since that period the study of this language has produced some good poets, who have generally dedicated their powers to the praises of their country, and to recording the merits of its most distinguished natives. As the subjects of their poetry are very little known beyond the limits of the country, we must trust to the reports of those who feel the most interest in the subjects of which it principally treats, and who, for that reason, may not be the most unbiassed critics.

The principal cities, and their population in 1834, were as follows:—

Pesth, with Buda or Ofen	95,000
Debreczin	46,000
Presburg	36,000
Theresienstadt	34,000
Szegedem	34,000
Misklaz	28,500
Nyir-Egybaza	20,000
Stuhlweisenburg	20,000
Komorn	18,500
Schemnitz	17,500
Raab	17,500
Grosswardein	17,000
Mako	17,000
Gyongyos	15,500
Boszormeny	15,000
Szathmar	14,500
Gyula	14,500
Fileghyaza	14,500
Kaschau	14,000
Odenburg	13,500

Esongrad	13,000
Temeswar	12,500
Gran	12,000
Szolnok	12,000
Pecs	11,500
Nagy-Karoly	11,500
Agram	11,500
Eszeck	11,500
Veszprim	10,500

The early history of this important kingdom is highly interesting, both as marking the tribes from Asia who established and finally spread themselves over the whole of Europe, and as illustrating the origin of that feudal system which ultimately produced the present state of civilization.

The inhabitants of this country are not to be confounded with those tribes called the Hunns, whom we are accustomed to consider as their progenitors, on account of the similarity of the names; a similarity which does not exist in their native language, but which has been given to them by foreigners.

The Hunns were, according to De Guignes's history of that people, a powerful but uneducated nation of Tartary, against whose incursions the great wall of China was constructed, about 209 years before the Christian era. In the time of Augustus they inhabited the shores of the Caspian Sea, from whence, being pressed westward by other tribes, they became the scourge of Europe, and gradually attained great power, which was at length wielded by Attila. But after his death in the year 453, the nation fell to ruin, though some of them were long to be found on the north of the Danube, and some on the shores of the Palus Mæotis, or Sea of Azoph, till at length their name totally disappeared.

The present people of Hungary, or, in their own language, the Magyars, made their first appearance in Europe in the year 894 of our era, having advanced from the southern shores of the Black Sea, under a leader named Almus. By himself and his son Arpad, the Bulgarians, the Slawen, the Wallachians, the Germans, Croatians, and Dalmatians, who were settled there, were either subdued, driven out, or extirpated, by the year 900. The land was at first divided amongst the heads of the several families; but in a short time the power was conceded to the chief, who assumed the title of duke, and the right of granting land to reward any deed of warlike merit.

The Magyars were no sooner in possession of the rich country, than their interference was requested by their rival neighbours for aid against each other; a request which, by such warriors, excited by their recent conquests, was not received with hesitation or delay. They soon extended their power in every direction by collecting a large and active body of cavalry, which was not to be resisted by any forces that could be collected to oppose them. They soon spread themselves, and in a few years were feelingly known to the north in Hamburg and Bremen, to the west in France, to the south in Otranto, and to the east at Constantinople. In the year 933 they first came, under their duke Zwenlibold, in contact with the Emperor of Germany, Henry I., whom they defeated in a great battle near Merseburg, on the river Saal, in Saxony. They penetrated into Franconia, but there, at Drommling on the Ohr, they met a severe repulse. In a subsequent incursion into Bavaria, after some early successes, they experienced a sanguinary defeat on the river Lech, from the German king Otho I., in the year 955. The continued attacks of the more civilized people of the west drove them in the course of a few years wholly out of Germany. As they became settled in their country, they gradually adopted more tranquil habits. They had learned something of the simplest arts of agriculture in the countries which they had invaded; and the numerous prisoners whom they had brought with them were made to cultivate the land, and to practise the simplest mechanic arts. This progress continued under one of their dukes, Taksony, who used his power to convince his followers that there were other ways of extending their authority than by warlike expeditions. Under Geysa or Geesa, the great-grandson of Arpad, who married Carolta, a Christian princess, an important event took place. He was celebrated for his hospitality, and invited foreigners to settle in his country; and, amongst others, he, at the instigation of his wife, called in some of the priests. By gradual steps their religion was also introduced; and in the year 973 Geysa and some thousands of his chief people embraced the Christian faith, and were admitted into the bosom of the church by a public baptism.

By the aid of the Bishop Pellegrin of Passau, and of the Bishop of Prague, Adelbert, he strove to overcome the reluctance felt by the greater part of his people to adopt the new religion. This task was left to his son and successor Stephen, who for his success in conversion, and for his extirpation of heathenism, was canonized after his death; and in his lifetime was presented by Pope Silvester II. with a crown, the remains of which are still preserved, a patriarchal crucifix, and the title of apostolic king. The throne of Hungary was thus founded in the year 1000, and was surrounded by an aristocracy and an hierarchy calculated to support it. The king endowed ten rich bishoprics, and divided his dominion into seventy-two countships (*gespanschafts*), over each of which was placed a chief, with full civil and military authority, in the exercise of which he was alone accountable to the monarch himself.

These nobles and prelates were formed into a senate, and, in conjunction with them, the king framed a constitution, which has in its groundwork existed to the present time. In the year 1002, the chief of Siebenburgen, named Gyula, remained in heathenism, and had contracted alliances with the yet unconverted subjects of Stephen. He was attacked and subdued, and his dominions added to the kingdom of Hungary. Stephen married a sister of the Emperor of Germany, Henry II.; and being thus connected, was universally acknowledged as a king, and the succession declared to be hereditary in his descendants. But he died leaving no issue, and for several years the kingdom was in a state of anarchy, some parts of it acknowledging one sovereign, and others a different one, and contending with greater violence, because during the contests the remains of heathenism still continued, and its adherents formed a powerful party. They were, however, suppressed by one of the race of their ancient kings, Ladislaus, who, in 1077, united in himself the supreme power, and added to its strength by conquering and enclosing within his dominions the provinces of Croatia and Sclavonia. In this course he was followed by his son Solaman, who increased his dominion in 1095 by the subjugation of Dalmatia and Bosnia. A daughter of this King Ladislaus, named Sophia, married a prince of the house of Hapsburg, Dukes of Austria; and it is through this lady that the present occupiers of the imperial throne trace their pedigree up to Arpad, one of the earliest founders of the kingdom of Hungary. Both these kings were of great benefit to the country, by the wise laws they introduced, and the internal regulations which they established. Under them and their successors colonists were introduced both from Flanders and from Alsace, and many Germans from various circles. These were mostly established in Siebenburgen; but everywhere they communicated better practices in cultivation, and in the various arts of civilized life. Belas II. one of their kings, who had been educated at the court of Byzantium, induced the Hungarians, who had been accustomed to pass the greater part of their time under tents, to build permanent houses, and to erect towns and cities, which were endowed with privileges; and, in imitation of what he had seen in the Greek capital, he established a court, with great offices of state, to give dignity and power to his throne.

In the year 1186, this Belas married Margaretta, daughter of Henry king of France, the widow of the son of Henry II. king of England. She brought with her to the Hungarian court some degree of French elegance, and induced several of the younger nobles to repair to Paris for their improvement in learning and in military exercises.

Under his successor Andreas II. the power of the great nobles was exercised to compel that weak prince to extend and strengthen their influence, and they extorted from him a treaty in their favour in 1223, which has been denominated the Golden Bull.

Belas IV. was anxious to make some alterations, and before he could adopt and prepare them, was interrupted by incursions from the Mongul tribes, who for a time spread devastation over a great part of the country. They were, however, ultimately repulsed, and the king restored to his authority. He then drew to Hungary a vast number of German colonists, which improved the state of civilization; and he founded several cities, fortified them, and conferred extensive privileges upon the burghers, who thus became in process of time a counterbalance to the power of the nobles. In 1241 his son Stephen was crowned as co-regent with the father. This gave rise to contests between the two sovereigns, by which the royal power suffered severely. Andreas IV. succeeded to the throne, and dying in 1301, the male line of the Arpad race became extinct. The female line gave the crown to the family of Anjou, under whose princes Hungary attained its highest pitch of prosperity and power. Louis, the first of the new dynasty, was the son of Robert, originally the Norman, who ruled in Sicily, and had married the Princess Elizabeth of Poland. Under this prince the thrones of Hungary and Poland were united, he having obtained the first in 1342, and the second on the death of his uncle in 1370, and became the greatest power in Europe, extending from the Adriatic to the Baltic Seas. The several public institutions were improved, the better cultivation of the soil was promoted, the administration of justice established, and cases which had before been decided by wager of battle determined by judges. This prince also endeavoured to introduce learning, and with that view established a university at Ofen, and a free school in Fünfkirchen. He relieved commerce from many burdensome imposts, and, according to the policy of the age, sought to preserve his subjects from heavy usury, by banishing all the Jews from his dominions.

Louis died without male issue, and his two daughters, Hedwig and Maria, divided his dominions. The former ascended the throne of Poland, and the latter that of Hungary. Maria married Siegmund, the son of the Emperor Charles IV. who, with his wife, was crowned in 1387.

Siegmund's reign was distinguished by his contests with the nobles, who held him a prisoner at one period, during which Red Russia was seized upon by the Poles, a portion of Dalmatia by the Venetian republic, and some parts of the eastern frontier by the Turks, who since their appearance began to annoy Hungary, which thus became the bulwark of Europe against the infidels. In this reign also commenced the religious wars of the Hussites. Siegmund left only a daughter, Elizabeth, who married the Archduke Albert of Austria; the latter died in 1436, leaving her pregnant with a son, Ladislaus, who bore the surname of Posthumus. He was declared king, and the government conducted by John de Hunoyed, who, under the title of stadtholder, saved Belgrade, and indeed Hungary, from the Turks. On attaining his majority in 1456, Ladislaus was dissatisfied with his great benefactor, and most unjustly persecuted his family. The eldest of the Hunyades was put to death, and the youngest, named Mathias, distinguished by the surname of Corvinus, was imprisoned. Ladislaus died in 1457, without issue, when Mathias seized on the vacant throne, and was confirmed in it by an assembly of the states collected at Pesth, in spite of the strong pretensions of the Emperor Frederick III.

Under the new reign great vigour was displayed. Mathias, though an elected king, knew how to emancipate himself from the dominion of those who had chosen him, as well as to oppose with success all external enemies. He recovered the provinces which had been lost by his predecessors, and by hostilities gained others. He drove the Turks out of Bosnia. In a war with George, king of Bohemia, he seized Moravia, Silesia, and Lausatia, and deprived the emperor himself of some of his provinces, especially of the land below the Ens. His active spirit enlivened commerce, improved agriculture, and formed excellent institutions for judicial and fiscal administration. To all his other watchful precautions he added that of maintaining a constant regularly-armed force.

This flourishing state of Hungary vanished speedily after the death of Mathias, when, in 1490, Wladislaus of Bohemia, the grandson of Albert and Elizabeth, was raised by the states to the throne. He had from the first powerful parties to contend with amongst the nobles, and at length a kind of servile war to engage in. The peasants rose in every part at the instigation of some amongst the nobles, and the insurrection was not quelled till 1512, and then only with the loss of the lives of 40,000 of these miserable people, and the condemnation of others to the condition of slaves.

During this reign Count John Zapolya raised a powerful faction in the assembly of the states, by proposing a law in 1505, to revive an ancient enactment, that in case of the death of a king without issue, the states should elect to the throne none but a native of Hungary. This attempt was frustrated by a treaty entered into with the emperor, and after the death of the king his son Ludwig succeeded him; but in an unhappy battle with the Turks at Mohacz in 1526, Ludwig fell, and Zapolya was declared by his party the successor to the throne. A larger party of the states, however, declared in favour of Ferdinand, who had married Anna, the daughter of Wladislaus. A civil war ensued, which drove Zapolya from the station he had assumed, and, as a denounced traitor, he fled to the Turks, by whose assistance he was enabled to make a predatory incursion, which was repressed after some time; and though Ferdinand, now become emperor, was fairly established, Zapolya was restored to his estates and his dignities, and the peasants who had lost their privileges by the insurrection of 1512 were re-instated in the rights they had before possessed. The want of success in the attempts of Zapolya has been attributed to his avowed persecution of heretics, by which the Protestants, who had become numerous, were induced to strengthen the party of the house of Austria, who, after being safely placed on the throne, were far from acting in conformity with the views of those who maintained that they had turned the scale in favour of that family.

At length, at an assembly of the states held in 1547, the hereditary right of the house of Austria to the throne of Hungary was solemnly established; and from that period the history of Hungary is included in that of the imperial house which long gave a succession of emperors to Germany, and has at length assumed the title of Emperors of Austria.

Hungary-*Water*, a distilled water prepared from the tops of flowers of rosemary, and so denominated from a queen of Hungary, for whose use it was first made.

HUNGER, an uneasy sensation occasioned by long abstinence from food when the body is in a healthy state. The following useful observations upon hunger or famine are extracted from a paper by Dr Percival in the second volume of the *Manchester Transactions.*

In a state of famine, life may be protracted, with less pain and misery, by means of a moderate allowance of water. For the acrimony and putrefaction of the humours are obviated by such dilution; the small vessels are kept permeable; and the lungs are furnished with that moisture which is essential to the performance of their functions. Fontanus, a writer of respectable authority in the estimation of Morgagni, relates the history of a woman who obstinately refused to take any sustenance, except twice, during the space of fifty days, at the end of which period she died. But he adds, that she used water by way of drink, though in small quantity. Redi, who made many experiments (cruel and unjustifiable in our opinion) to ascertain the effects of fasting on fowls, observed that none were able to support life beyond the ninth day to whom drink was denied, whereas one indulged with water lived more than twenty days.

Hippocrates has observed, that children are more affected by abstinence than young persons, these more than the middle-aged, and the middle-aged more than old men. The power to endure famine, however, must depend no less upon the state of health and strength than upon the age of the sufferer. There are also particular constitutions which do not suffer much pain from the calls of hunger. Dr Percival was informed by a young physician from Geneva, that when he was a student at Montpellier he fasted three nights and four days, with no other refreshment than a pint of water daily. His hunger was keen, but never painful, during the first and second days of his abstinence; and the two following days he perceived only a faintness when he attempted either bodily or mental exertion. A sense of coldness was diffused over his whole frame, but more particularly affected the extremities. His mind was in a very unusual state of pusillanimity; and he experienced a great tendency to tears whenever he recollected the circumstance which had been the occasion of his fasting. During the whole period, the alvine excretions were suppressed, but not those by the kidneys; and at the close of it his skin became tinged with a shade of yellow. The first food he took was veal broth, which had something of an intoxicating effect, producing a glow of warmth, and raising his spirits, so as to render him ashamed of his despondency. Perhaps, in the case of Sextius Baculus, as recorded in the Commentaries of Cæsar (lib. vi.), the extraordinary courage and prowess which he suddenly exerted might be aided by the exhilarating effect of sustenance, which, under such circumstances, it is probable he would no longer decline. The fact, however, evinces that neither his sickness nor the sensations of hunger had been so violent as much to impair his strength of body or vigour of mind. Pomponius Atticus, the celebrated friend of Cicero, who put a voluntary end to his life in the seventy-seventh year of his age by refusing all food, appears to have experienced ease from his disorder, rather than any acute sufferings, by famine. "Sic cum biduo cibo se abstinuisset, subito febris decessit, leviorque morbus esse cœpit; tamen propositum nihilo secius peregit. Itaque die quinto, postquam id consilium inierat, decessit."[1] From the former circumstance, it has been conjectured that he did not wholly deny himself the use of water, or of some other diluent. But though a few examples of this kind may be produced, we have the evidence of numerous melancholy facts to show that the pressure of want is agonizing to the human frame. "I have talked," says an ingenious writer,[2] "with a captain of a ship who was one of six that endured it in its extremity, and who was the only person that had not lost his senses when they received accidental relief. He assured me his pains at first were so great as to be often tempted to eat a part of one of the men who died, and which the rest of his crew actually for some time lived upon. He said that, during the continuance of this paroxysm, he found his pains insupportable, and was desirous at one time of anticipating that death which he thought inevitable. But his pains, he said, gradually decreased after the sixth day (for they had water in the ship, which kept them alive so long), and then he was in a state rather of languor than desire; nor did he much wish for food, except when he saw others eating; and that for a while revived his appetite, though with diminished importunity. The latter part of the time, when his health was almost destroyed, a thousand strange images rose upon his mind, and every one of his senses began to bring him wrong information. The most fragrant perfumes appeared to him to have a fetid smell; and every thing he looked at took a greenish hue, and sometimes a yellow. When he was presented with food by the ship's company that took him and his men up, four of whom died shortly after, he could not help looking upon it with loathing instead of desire; and it was not till after four days that his stomach was brought to its natural tone, when the violence of his appetite returned with a sort of canine eagerness."

To those who by their occupations are exposed to such dreadful calamities, it is of serious importance to be instructed in the means of alleviating them. The American Indians are said to use a composition of the juice of tobacco, and the shells of snails, cockles, and oysters calcined, whenever they undertake a long journey, and are likely to be destitute of provisions. It is probable the shells are not burned into quicklime, but only so as to destroy their tenacity, and to render them fit for levigation. The mass is dried, and formed into pills of a proper size to be held between the gum and lip, which, being gradually dissolved and swallowed, deaden the sensations both of hunger and of thirst. Tobacco, by its narcotic quality, seems well adapted to counteract the uneasy impressions which the gastric juice makes on the nerves of the stomach when it is empty; and the combination of testaceous powder with it may tend to correct the secretion that is supposed to be the chief agent in digestion, and which, if not acid, is always united with acidity. Certain at least it is, that their operation is both grateful and salutary; for we find the luxurious inhabitants of the East Indies mix them with the betel-nut, to the chewing of which they are universally and immoderately addicted. Perhaps such absorbents may be usefully applied, both to divide the doses and to moderate the virulence of the tobacco. For, in the internal exhibition of this plant, much caution is required, as it produces sickness, vertigo, cold clammy sweats, and a train of other formidable symptoms, when taken in too large a quantity. During the time of war, the impressed sailors frequently bring on these maladies that they may be admitted into the hospitals, and released from servitude. It would be an easy and safe experiment to ascertain the efficacy and to adjust the ingredients of the Indian composition mentioned; and there is reason to believe that the trial would be in some degree successful; for it is known that smoking tobacco gives relief to those habitual pains of the stomach which appear to arise from the irritation of the gastric secretion. The like effect is sometimes produced by increasing the flow of saliva, and swallowing what is thus discharged. And Dr Percival has related the case of a gentleman who used to masticate, many hours daily, a piece of lead, which being neither hard, friable, nor offensive to the palate, suited his purpose, as he thought, better than any other substance. He continued the custom for many years, deriving great ease from it, and suffering no sensible injury from the poisonous quality of the metal. On mentioning this fact to a navy surgeon, the doctor was told that the sailors, when in hot climates, are wont to mitigate thirst by rolling a bullet in their mouths. A more innocent mean, the doctor observes, might be devised; but the efficacy of this evinces, that the salivary glands are for a while capable of furnishing a substitute for drink. When a scarcity of water occurs at sea, Dr Franklin has advised that the mariners should bathe themselves in tubs of salt water. For, in pursuing the amusement of swimming, he observed, that however thirsty he was before immersion, he never continued so afterwards; and that, though he soaked himself several hours in the day, and several days successively, in salt water, he perceived not, in consequence of it, the least taste of saltness in his mouth. He also further suggests, that the same good effect might perhaps be derived from dipping the sailors' apparel in the sea, and expresses a confidence that no danger of catching cold would ensue.

[2] Dr Goldsmith's *History of the Earth*, vol. ii. p. 126.

To prevent the calamity of famine at sea, it has been proposed by Dr Lind, that the powder of salep should constitute part of the provisions of every ship's company. This powder and portable soup, dissolved in boiling water, form a rich thick jelly; and an ounce of each of these articles furnishes one day's subsistence to a healthy full-grown man. Indeed, from Dr Percival's experiments it appears, that salep contains more nutritious matter, in proportion to its bulk, than any other vegetable production now used as food. It has the property also of concealing the nauseous taste of salt water; and consequently may be of great advantage at sea, when the stock of fresh water is so far consumed that the mariners are put upon short allowance. By the same mucilaginous quality, it covers the offensiveness, and even in some measure corrects the acrimony, of salted and putrescent meats. But, as a preservative against hunger, salep would be most efficaciously combined with an equal weight of beef suet. By swallowing little balls of this lubricating compound at proper intervals, the coats of the stomach would be defended from irritation; and as oils and mucilages are highly nutritive, of slow digestion, and indisposed to pass off by perspiration, they are peculiarly well adapted to support life in small quantities. This composition is superior in simplicity, and perhaps equal in efficacy, to the following one, so much extolled by Avicenna the celebrated Arabian physician, to whom we are indebted for the introduction of rhubarb, cassia, tamarinds, and senna, into the materia medica. "Take sweet almonds and beef suet, of each one pound; of the oil of violets two ounces; and of the roots of marshmallows one ounce; bray these ingredients together in a mortar, and form the mass into boluses about the size of a common nut." Animal fat is singularly powerful in assuaging the most acute sensations of thirst, as appears from the narrative of the sufferings experienced by those who were confined in the black hole at Calcutta. A hundred and forty-six persons, exhausted by fatigue and military duty, were there thrust together into a chamber of eighteen cubic feet, having only two windows, strongly barred with iron, from which, in a close sultry night, and in such a climate as that of Bengal, little or no circulation of fresh air could be enjoyed. In a few minutes these unhappy wretches fell into such a profuse perspiration, that an idea can hardly be formed of it; and this again was succeeded by a raging thirst, which increased in proportion as the body was drained of its moisture. Water, water, became the universal cry; and an old soldier on the outside, through pity, furnished them with a few skinfuls of it. But these scanty supplies, like sprinklings thrown on the fire, served only to feed and increase the flame. From this experience of its effects, Mr Holwell, their chief, determined to drink no more, and kept his mouth moist by sucking the perspiration out of his shirt sleeves, and catching the drops as they fell from his head and face. "You cannot imagine," says he, "how unhappy I was if any of them escaped me." He came into the prison without his coat, the season being too hot to bear it; and one of his miserable companions, observing the expedient he had hit upon of allaying his thirst, robbed him from time to time of a considerable part of his store. This plunderer, whom he found to be a young gentleman in the service of the East India Company, afterwards acknowledged that he owed his life to the many comfortable draughts which he derived from him. Before Mr Holwell adopted this mode of relief, he had attempted, in an ungovernable fit of thirst, to drink his own urine; but it was so intensely bitter that a second taste could not be endured; whereas, he assures us, no Bristol water could be more soft and pleasant than his perspiration. And this, we may presume, consisted chiefly of animal fat, melted by excessive heat, and exuding from the cellular membrane through the pores of the skin.

Persons who have been accustomed to animal food are soon reduced when supplied only with the farinacea. Several years ago, to determine the comparative nutritive powers of different substances, an ingenious young physician, as Dr Percival informs us, made a variety of experiments on himself, to which he unfortunately fell a sacrifice. He lived a month upon bread and water; and under this regimen of diet he every day diminished much in his weight.

In attempts to recover those who have suffered under the calamities of famine, great circumspection is required. Warmth, cordials, and food, are the means to be employed; and it is evident that these may prove too powerful in their operation, if not administered with caution and judgment. For the body, by long fasting, is reduced to a state of more than infantile debility; the minuter vessels of the brain, and of the other organs, collapse for want of fluids to distend them; the stomach and intestines shrink in their capacity; and the heart languidly vibrates, having scarcely sufficient energy to propel the scanty current of blood. Under such circumstances, a proper application of heat seems an essential measure, and may be effected by placing on each side a healthy man in contact with the patient. Pediluvia or fomentations may also be used with advantage. The temperature of these should be lower than that of the human body, and gradually increased according to the effects of their stimulus. New milk, weak broth, or water gruel, ought to be employed both for the one and the other; as nutriment may be conveyed into the system this way, by passages probably the most pervious in a state of fasting, if not too long protracted. "A lad at Newmarket[1] having been almost starved in order that he might be reduced to a proper weight for riding a match, was weighed at nine o'clock in the morning, and again at ten; and he was found to have gained near thirty ounces in weight in the course of an hour, though he had only drank half a glass of wine in the interval. The wine probably stimulated the action of the nervous system, and incited nature, exhausted by abstinence, to open the absorbent pores of the whole body, in order to suck in some nourishment from the air." But no such absorption as this can be expected in a state of extreme weakness and emaciation gradually induced, because the lymphatics must partake of the general want of tone and energy. And notwithstanding the salutary effects of wine in the case of the jockey, who, it is likely, had been reduced by sweating as well as by abstinence, such a stimulant might prove dangerous, and even fatal, in other cases. It appears safer to advise the exhibition of cordials in very small doses, and at first considerably diluted. Slender wine whey will perhaps best answer this purpose, and afford, at the same time, an easy and pleasant nourishment. When the stomach has been a little strengthened, an egg may be mixed with the whey, or administered under some other agreeable form. The yolk of one was, to Cornaro, sufficient for a meal; and the narrative of this noble Venetian, in whom a fever was excited by the addition of only two ounces of food to his daily allowance, shows that the return to a full diet should be conducted with great caution, and by very slow gradations.

[1] Watson's *Chemical Essays*, vol. iii. p. 101.

HUNGERFORD, a market-town of the county of Wilts, in the hundred of Kentbury, but a part of it is within the county of Berks. It is sixty-eight miles from London, on the road to Bath, and is watered by the river Kennet. It has some trade by the Kennet and Avon Canal, both with London and with Bristol. There is a market, which is held on Wednesday. The church is a very ancient building.

HUNINGEN, a town of the arrondissement of Altkirch, in the department of the Upper Rhine, in France. It is on the Rhine, and was strongly fortified till 1815; and being within two miles of the Swiss frontier, was deemed of military importance, as commanding the river. It contains about 1000 inhabitants. Long. 7. 30. E. Lat. 47. 42. N.

HUNNS, a fierce and savage nation, who formerly inhabited that part of Sarmatia bordering on the Palus Mæotis and the Tanais, the ancient boundary between Europe and Asia. Their country, as described by Procopius, lay north of Mount Caucasus, which, extending from the Euxine to the Caspian Seas, separates Asiatic Sarmatia from Colchis, Iberia, and Albania, and occupies the isthmus between the two seas above mentioned. Here they resided, unknown to other nations, and themselves ignorant of other countries, till the year 376. At this time, a hind pursued by the hunters, or, according to some authors, an ox stung by a gad-fly, having passed the marsh, was followed by some Hunns to the other side, where they discovered a country much more agreeable than their own. On their return, having acquainted their countrymen with what they had seen, the whole nation passed the marsh, and having attacked the Alans, who dwelt on the banks of the Tanais, almost exterminated them. They next fell upon the Ostrogoths, whom they drove out of their country, and forced to retire to the plains between the Borysthenes and the Tanais, now known by the name of Podolia. They next attacked the Visigoths, whom they obliged to shelter themselves in the most mountainous parts of their country; and at last the Gothic nations, finding it impossible to withstand such an inundation of barbarians, obtained leave from the Emperor Valens to settle in Thrace.

The Hunns thus became in 376 masters of all the country between the Tanais and Danube, where they continued quietly till the year 388, when great numbers of them were taken into the pay of Theodosius I.; but, in the mean time, a party of them, called the Nephthalite or White Hunns, who had continued in Asia, overran all Mesopotamia, and even laid siege to Edessa, where they were repulsed with great slaughter by the Romans. The European Hunns frequently passed the Danube, and committed the greatest ravages in the western empire; sometimes they also fell upon the eastern provinces, where they put all to fire and sword. They were often defeated and repulsed by the Romans; but the empire was now too weak to subdue or prevent them from making excursions; so that they continued to make encroachments, and became every day more formidable than before. In 411, the Hunns, under Attila, threatened the western empire with total destruction. This monarch, having made himself master of all the northern countries from the confines of Persia to the banks of the Rhine, invaded Mæsia, Thrace, and Illyricum, and made such progress, that the emperor not thinking himself safe at Constantinople, withdrew into Asia. Attila then broke into Gaul, where he took and destroyed several cities, and massacred the inhabitants with the greatest cruelty. At last he was driven out with great slaughter by Ætius the Roman general, and Theodoric king of the Goths, and could never afterwards make any great progress. About the year 452 or 453 Attila died, and his kingdom was immediately split into a number of small ones by his numerous children, who waged perpetual war with one another. The Hunns then ceased to be formidable, and became daily less able to cope with the other barbarous nations whom Attila had kept in subjection. Still, however, their dominion was considerable; and in the time of Charles the Great they were masters of Transylvania, Wallachia, Servia, Carniola, Carinthia, and the greater part of Austria, together with Bosnia, Sclavonia, and that part of Hungary which is situated beyond the Danube. In the year 776, whilst Charles was in Saxony, two princes of the Hunns, Caganus and Jugunus, sent ambassadors to him, desiring his friendship and alliance. Charles received them with extraordinary marks of friendship, and readily complied with their request. However, they not long afterwards entered into an alliance with Taffila duke of Bavaria, who had revolted from Charles, and raised great disturbances in Germany. Charles dissembled his resentment till he had entirely reduced Bavaria, when he resolved to revenge himself on the Hunns for the underhand succours they had given to his enemy. Accordingly, he ordered levies to be made throughout his dominions, and having assembled a very numerous army, divided it into two bodies, one of which he commanded himself, and the other he committed to the care of his generals. The two armies entered the kingdom of the Hunns at different places, ravaged their country far and wide, burned their villages, and took all their strongholds. This he continued for eight years, till the people were almost totally extirpated; nor did the Hunns ever afterwards recover the blow, or appear as a distinct nation.

There were two different nations which went by the name of Hunns; the Nephthalite or White Hunns, and the Sarmatian or Scythian Hunns. The former inhabited a rich country bordering to the north on Persia, and at a great distance from the Sarmatian or Scythian Hunns, with whom they had no intercourse, nor the least resemblance either in their persons or manners. They were a powerful nation, and often served against the Romans in the Persian armies; but in the reign of the Emperor Zeno, being provoked by Perozes king of Persia laying claim to part of their country, they defeated the Persians in two pitched battles, slew their king, overran all Persia, and held it in subjection for the space of two years, obliging Cabades, the son and successor of Perozes, to pay them an annual tribute. These Hunns, called by the writers of those times the White Hunns, did not wander, like the others, from place to place; but, contented with their own country, which supplied them with all necessaries, they lived under a regular government, subject to one prince, and seldom made inroads, unless provoked, either into the Persian or Roman territories. They lived according to their own laws, and dealt uprightly with one another, as well as with the neighbouring tribes. Each of their great men used to choose twenty or more companions to enjoy with him his wealth, and partake of all his diversions; but, upon his decease, they were all buried with him in the same grave. This custom savours of extreme barbarity; but in every other respect the Nephthalite were a less ferocious race than the Scythian Hunns, who, breaking into the empire, filled most of the provinces of Europe with blood and slaughter.

The latter were, according to Ammianus Marcellinus, a savage race, exceeding in cruelty the most barbarous nations. According to Jornandes, they began to practise their cruelty upon their own children the very first day they came into the world, cutting and mangling the cheeks of their males, to prevent the growth of hair, which, contrary to the sentiments of other nations, they must have looked upon as unbecoming and unmanly. They had, perhaps, in this practice another view, which Jornandes seems to insinuate elsewhere, namely, to strike terror into the enemy with their countenances thus deformed and covered with scars. They had no other food but roots and raw meat, being quite unacquainted with the use of fire; they had no houses at all, not even huts; they lived constantly exposed to the air, in the woods and on the mountains, where, from their infancy, they were inured to hunger, thirst, and all manner of hardships; and they had such an aversion to houses, which they called the sepulchres of the living, that, when they migrated into other countries, they could hardly be prevailed upon to come within the walls of any house, not thinking themselves safe when shut up and covered. They used even to eat and sleep on horseback, scarcely ever dismounting; a circumstance which, in all likelihood, induced Zosimus to assert that the Hunns could not walk. They covered their nakedness with goats' skins, or the skins of a sort of mice sewed together. Day and night were indifferent to them, as to buying, selling, eating, and drinking. They had no law, nor any kind of religion, but complied with their inclinations, whenever these prompted them, without the least restraint, or distinction between good and evil. In war they began the battle with great fury and a hideous noise; but if they met with a vigorous opposition, their fury began to abate after the first onset; and when once put into disorder, they never rallied, but fled in the utmost confusion. They were quite unacquainted with the art of besieging towns; and authors observe, that they seldom or never attacked the enemy's camp. They were a faithless nation, and thought themselves no longer bound by the most solemn treaties than they found their advantage in observing these. Hence we often find them, upon the least prospect of obtaining more advantageous conditions, breaking into the Roman empire, in defiance of the most solemn oaths and engagements. Several corps of Hunns, after their coming into Europe, served in the Roman armies against the Goths and other nations; nay, they were ready for hire to fight against each other, being blind to every consideration excepting that of interest. For further information on this subject, the reader is referred to the learned and profound work of De Guignes, of which some account is given in the biographical notice of the author. See article GUIGNES.

HUNTER, a name given to a horse qualified to carry a person in the chase. See HORSE.

HUNTER, *Dr William*, a celebrated anatomist and physician, was born on the 23d of May 1718, at Kilbride, in the county of Lanark, in Scotland. He was the seventh child of John and Agnes Hunter, who resided on a small estate in that parish called Long Calderwood, which had been long in the possession of his family. His great grandfather by his father's side was a younger son of Hunter of Hunterston, chief of the family of that name. At the age of fourteen his father sent him to the College of Glasgow. In this seminary he passed five years, and by his prudent behaviour and diligence acquired the esteem of the professors, and the reputation of being a good scholar. His father had designed him for the church; but the idea of subscribing to articles of faith was so repugnant to the liberal mode of thinking which he had already adopted, that he felt an insuperable aversion to theological pursuits. In this state of mind he happened to become acquainted with Dr Cullen, afterwards so celebrated as professor at Edinburgh, who was then just established in practice at Hamilton under the patronage of the Duke of Hamilton. Dr Cullen's conversation soon determined him to lay aside all thoughts of the church, and to devote himself to the profession of physic. His father's consent having been previously obtained, Mr Hunter in 1737 went to reside with Dr Cullen. In the family of this excellent friend and preceptor he passed nearly three years; and these, as he was often heard to acknowledge, were the happiest of his life. It was then agreed that he should go to prosecute his medical studies at Edinburgh and London, and afterwards return to settle at Hamilton in partnership with Dr Cullen. He accordingly set out for Edinburgh in November 1740, and continued there till the following spring, attending the lectures of the medical professors, and amongst others those of Dr Alexander Monro, who, many years afterwards, in allusion to this circumstance, styled himself his old master.

Mr Hunter arrived in London in the summer of 1741, and took up his residence at the house of Dr Smellie, who was at that time an apothecary in Pall Mall. He brought with him a letter of recommendation to Dr James Douglas, from Mr Foulis, printer in Glasgow, who had been useful to the doctor in collecting for him different editions of Horace. Dr Douglas was then intent on a great anatomical work on the bones, which he did not live to complete, and was looking out for a young man of abilities and industry whom he might employ as a dissector. This induced him to pay particular attention to Mr Hunter; and finding him acute and sensible, he desired him to make him another visit. A second conversation confirmed the doctor in the good opinion he had formed of Mr Hunter; and without any further hesitation he invited him into his family to assist in his dissections, and to superintend the education of his son. Mr Hunter having accepted Dr Douglas's invitation, was by his friendly assistance enabled to enter himself as a surgeon's pupil at St George's Hospital under Mr James Wilkie, and as a dissecting pupil under Dr Frank Nichols, who at that time taught anatomy with considerable reputation. He likewise attended a course of lectures on experimental philosophy delivered by Dr Desaguliers. Of these means of improvement he did not fail to make a proper use. He soon became expert in dissection, and Dr Douglas was at the expense of having several of his preparations engraved. But before many months had elapsed, he had the misfortune to lose this excellent friend. The death of Dr Douglas, however, made no change in the situation of our author. He continued to reside with the doctor's family, and to pursue his studies with the same diligence as before.

In 1743 he communicated to the Royal Society an essay upon the structure and diseases of articulating cartilages. This ingenious paper, on a subject which till then had not been sufficiently investigated, affords a striking testimony of the rapid progress he had made in his anatomical inquiries. As he had it in contemplation to teach anatomy, his attention was directed principally to this object; and it deserves to be mentioned as an additional mark of his prudence, that he did not precipitately engage in the attempt, but passed several years in acquiring such a degree of knowledge, and such a collection of preparations, as might ensure his success. Dr Nichols, to whom he communicated his scheme, and who about that time declined giving lectures in favour of Dr Lawrence, did not give him much encouragement to prosecute it. But at length an opportunity presented itself for the display of his abilities as a teacher. A society of navy surgeons had an apartment in Covent Garden, where they engaged the late Mr Samuel Sharpe to deliver a course of lectures on the operations of surgery. Mr Sharpe continued to repeat this course, till finding that it interfered too much with his other engagements, he declined the task in favour of Mr Hunter, who gave the society so much satisfaction that they requested him to extend his plan to anatomy, and at first he had the use of their room for his lectures. This happened in the winter of 1746. He is said to have experienced much solicitude when he began to speak in public; but the applause he met with soon inspired him with courage; and by degrees he became so fond of teaching, that for many years before his death he was never happier than when employed in delivering a lecture. The profits of his first two courses were considerable; but, by contributing to the wants of different friends, he found himself at the return of the next season obliged to defer his lectures for a fortnight, merely because he had not money enough to defray the necessary expense of advertisements.

In 1747 he was admitted a member of the corporation of surgeons; and in the spring of the following year, soon after the close of his lectures, he set out, in company with his pupil Mr James Douglas, on a tour through Holland and France. His lectures suffered no interruption by this journey, as he returned to England soon enough to prepare for his winter course, which commenced about the usual time.

At first he practised both surgery and midwifery; but to the former of these he had always an aversion. His patron, Dr James Douglas, had acquired considerable reputation in midwifery; and this probably induced Mr Hunter to direct his views chiefly to the same line of practice. His being elected one of the surgeon-accoucheurs, first to the Middlesex, and soon afterwards to the British Lying-in Hospital, assisted in bringing him forward in this branch of his profession, in which he was recommended by several of the most eminent surgeons of that time, who respected his anatomical talents, and wished to encourage him. But these were not the only circumstances which contributed to his success. He owed much to his abilities, and much to his person and manner, which eminently qualified him for the practice of midwifery.

In 1750 he seems to have entirely relinquished his views in surgery, as in that year he obtained the degree of doctor of physic from the university of Glasgow, and began to practise as a physician. About this time he quitted the family of Mrs Douglas, and went to reside in Jermyn Street. In the summer of 1751 he revisited his native country, for which he always retained a cordial affection. His mother was still living at Long Calderwood, which had now become his property by the death of his brother James. Dr Cullen, for whom he always entertained a sincere regard, was then established at Glasgow, and had acquired considerable reputation both as a practitioner and teacher of physic; so that the two friends had the pleasure of being able to congratulate each other on their mutual prosperity. During this visit he showed his attachment to his little paternal inheritance by giving many instructions for repairing and improving it, and for purchasing any adjoining lands that might be offered for sale. After this journey to Scotland, to which he devoted only a few weeks, he was never absent from London, unless his professional engagements, as sometimes happened, required his attendance at a distance from the capital.

In 1755, on the resignation of Dr Layard, one of the physicians of the British Lying-in Hospital, we find the governors of that institution voting their "thanks to Dr Hunter for the services he had done the hospital, and for his continuing in it as one of the physicians;" so that he seems to have been established in this office without the usual form of an election. The year following he was admitted as a licentiate of the Royal College of Physicians. Soon afterwards he was elected a member of the Medical Society; and to the *Observations and Inquiries* published by that society he at different periods contributed several valuable papers.

In 1762 we find him warmly engaged in controversy, supporting his claim to different anatomical discoveries, in a work entitled *Medical Commentaries,* the style of which is correct and spirited. As an excuse for the tardiness with which he brought forward this work, he observes in his introduction that it required a good deal of time, and he had little to spare; that the subject was unpleasant, and therefore he was very seldom in the humour to take it up. In this publication he confined himself chiefly to a dispute with the professor of anatomy at Edinburgh, concerning injections of the testicle, the ducts of the lachrymal gland, the origin and use of the lymphatic vessels, and absorption by veins. He likewise defended himself against a reproach which Professor Monro senior had cast upon him, by giving a concise account of a controversy he was involved in with Mr Pott, concerning the discovery of the *hernia congenita.* It was not long before Mr Pott took occasion to give the public his account of the dispute; and, in reply, Dr Hunter added a supplement to his Commentaries. No man was ever more tenacious than Dr Hunter of what he conceived to be his anatomical rights. This was particularly evinced in the year 1780, when his brother communicated to the Royal Society a discovery he had made twenty-five years before, relative to the structure of the placenta, the communication between it and the uterus, and the vascularity of the spongy chorion. At the next meeting of the society a letter was read, in which Dr Hunter put in his claim to the discovery in question. This letter was followed by a reply from Mr John Hunter, and here the dispute ended.

In 1762, when the queen became pregnant, Dr Hunter was consulted; and two years afterwards he had the honour to be appointed physician extraordinary to her majesty. About this time his avocations were so numerous that he became desirous of lessening his fatigue; and having noticed the ingenuity and assiduous application of Mr William Hewson, who was then one of his pupils, he engaged him first as an assistant, and afterwards as a partner, in his lectures. This connection continued till the year 1770, when some dispute happened which terminated in a separation. Mr Hewson was succeeded in the partnership by Mr Cruikshank, whose anatomical abilities were deservedly respected.

In 1767 Dr Hunter was elected a fellow of the Royal Society, and in the year following communicated to that learned body observations on the bones, commonly supposed to be elephants' bones, which have been found near the river Ohio in America. This was not the only subject of natural history on which our author employed his pen; for, in a subsequent volume of the Philosophical Transactions, we find him offering his remarks on some bones found in the rock of Gibraltar, and which he proves to have belonged to some quadruped. In the same work, likewise, he published an account of the nyl-ghau, an Indian animal not described before. In 1768, Dr Hunter became a fellow of the Society of Antiquaries; and the same year, at the institution of a Royal Academy of Arts, he was appointed by his majesty to the office of professor of anatomy. This appointment opened a new field for his abilities; and he engaged in it, as he did in every other pursuit of his life, with unabating zeal. He now adapted his anatomical knowledge to the subjects of painting and sculpture; and the novelty and justness of his observations proved at once the readiness and extent of his genius. In January 1781 he was unanimously elected to succeed the late Dr John Fothergill as president of the Medical Society. As his name and talents were known and respected in every part of Europe, so the honours conferred upon him were not limited to his own country. In 1780, the Royal Medical Society at Paris elected him one of their foreign associates; and in 1782 he received a similar mark of distinction from the Royal Academy of Sciences in that city.

The most splendid of Dr Hunter's medical publications was the Anatomy of the Human Gravid Uterus. The appearance of this work, which had been begun as early as the year 1751 (when ten of the thirty-four plates it contains were completed), was retarded till the year 1775, in consequence of the author's desire of sending it into the world with fewer imperfections. This great work is dedicated to the king. In his preface to it, we find the author very candidly acknowledging, that in most of the dissections he had been assisted by his brother Mr John Hunter, "whose accuracy," he adds, "in anatomical researches is so well known, that to omit this opportunity of thanking him for that assistance would be in some measure to disregard the future reputation of the work itself." He likewise confesses his obligations to the ingenious artists who made the drawings and engravings; "but particularly to Mr Strange, not only for having by his hand secured a sort of immortality to two of the plates, but for having given his advice and assistance in every part with a steady and disinterested friendship."

When Dr Hunter began to practise midwifery, he was desirous of acquiring a fortune sufficient to place him in easy and independent circumstances. Before many years had elapsed, he found himself in possession of a sum adequate to his wishes in this respect; and this he set apart as a resource of which he might avail himself whenever age or infirmities should oblige him to retire from business. After he had attained this competency, as his wealth continued to accumulate, he formed a laudable design of engaging in some scheme of public utility, and at first had it in contemplation to found an anatomical school in the metropolis. For this purpose, during the administration of Mr Grenville, he presented a memorial to that minister, in which he requested the grant of a piece of ground in the Mews, for the site of an anatomical theatre. Dr Hunter undertook to expend L.7000 on the building, and to endow a professorship of anatomy in perpetuity. This scheme did not meet with the reception it deserved. In a conversation on this subject, which he had soon afterwards with the Earl of Shelburne, his lordship expressed a wish that the plan might be carried into execution by subscription, and very generously requested to have his name set down for a thousand guineas. Dr Hunter's delicacy would not allow him to adopt this proposal. He chose rather to execute it at his own expense, and accordingly purchased a spot of ground in Great Windmill Street, where he erected a spacious house, to which he removed from Jermyn Street. In this building, besides a handsome amphitheatre and other convenient apartments for his lectures and dissections, there was one magnificent room, fitted up with great elegance and propriety as a museum. Of the magnitude and value of his anatomical collection some idea may be formed, when we consider the number of years he employed in making the anatomical preparations, and in the dissection of morbid bodies, added to the eagerness with which he procured additions from the collections of Sandys, Hewson, Falconer, Blackall, and others, that were at different times offered for sale in this metropolis. His specimens of rare diseases were likewise frequently increased by presents from his medical friends and pupils; who, when any thing of this sort occurred to them, very justly thought they could not dispose of it more properly than by placing it in Dr Hunter's museum. Speaking of an acquisition in this way in one of his publications, he says, "I look upon every thing of this kind which is given to me, as a present to the public; and consider myself as thereby called upon to serve the public with more diligence."

Before his removal to Windmill Street, he had confined his collection chiefly to specimens of human and comparative anatomy, and of diseases; but now he extended his views to fossils, and likewise to the promotion of polite literature and erudition. In a short space of time he became possessed of a most magnificent collection of Greek and Latin books. A cabinet of ancient medals contributed likewise much to the richness of his museum. A description of part of his coins in this collection, struck by the Greek free cities, was afterwards published by the doctor's learned friend Mr Combe. In the preface some account is given of the progress of the collection, which has been brought together since the year 1770, with singular taste, and at the expense of upwards of L.20,000. In 1781, the museum received a valuable addition of shells, corals, and other curious subjects of natural history, which had been collected by the late worthy Dr Fothergill, who gave directions by his will, that his collection should be appraised after his death, and that Dr Hunter should have the refusal of it at L.500 under the valuation. This was accordingly done, and Dr Hunter purchased it for the sum of L.1200.

Dr Hunter, at the head of his profession, honoured with the esteem of his sovereign, and in possession of every thing that his reputation and wealth could confer, seemed now to have attained the summit of his wishes. But these sources of gratification were embittered by a disposition to the gout, which harassed him frequently during the latter part of his life, notwithstanding his very abstemious manner of living. On Saturday the 15th of March 1783, after having for several days experienced a return of a wandering gout, he complained of great headach and nausea. In this state he went to bed, and for several days felt more pain than usual, both in his stomach and limbs. On the Thursday following he found himself so much recovered, that he determined to give the introductory lecture to the operations of surgery. It was to no purpose that his friends urged to him the impropriety of such an attempt. He was determined to make the experiment, and accordingly delivered the lecture; but towards the conclusion his strength was so exhausted that he fainted away, and was obliged to be carried to bed by two servants. During the night and the following day his symptoms were such as indicated danger; and on Saturday morning, Mr Combe, who made him an early visit, was alarmed on being told by Dr Hunter himself, that during the night he had certainly had a paralytic stroke. As neither his speech nor his pulse were affected, and he was able to raise himself in bed, Mr Combe encouraged him to hope that he was mistaken. But the event proved the doctor's idea of his complaint to be but too well founded. He died on Sunday the 30th of March 1783.

By his will, the use of his museum, under the direction of trustees, devolved to his nephew Dr Matthew Baillie, and in case of his death, to Mr Cruikshank, for the term of thirty years; at the end of which period the whole collection was bequeathed to the university of Glasgow, where it is now deposited.

HUNTER, *John*, an eminent surgeon, was the youngest child of John Hunter of Kilbride, in the county of Lanark. He was born at Long Calderwood on the 13th of July 1728. His father died when he was about ten years of age, from which circumstance his mother was induced to grant him too much indulgence. In consequence he made no progress at the grammar school, and was almost wholly illiterate at the age of twenty, when he arrived in London. His brother Dr W. Hunter was at that time the most eminent teacher of anatomy, and John expressed a wish to attend him in his researches. The doctor, anxious to make trial of his talents, gave him an arm to dissect for the muscles, with proper instructions how it was to be performed; and the dexterity with which he managed his undertaking exceeded the expectations of his brother.

Having acquired some reputation from this first attempt, his brother employed him in a more difficult dissection, which was an arm in which all the arteries were injected, and these and the muscles were to be preserved and exposed. In the execution of this task he also gave the highest satisfaction, and his brother predicted that he would become a good anatomist, and never want employment. Under the instructions of his brother, and Mr Symonds his assistant, he enjoyed every favourable opportunity of increasing his anatomical knowledge, since that school monopolized all the dissections then carried on in London.

He was admitted into partnership with his brother in the winter of 1755, and a certain department of the lectures was allotted to him; and he also lectured when the doctor was called away to attend his patients. The mind of Mr Hunter was peculiarly fitted for the study of anatomy, and the indefatigable ardour with which he prosecuted it is scarcely to be equalled. He applied to human anatomy for ten years, during which period he made himself master of every thing then known, and also made some considerable additions. He was the first who discovered the existence of the lymphatic vessels in birds.

In 1760 his friends advised him to go abroad, as he exhibited many symptoms of an incipient consumption. In October that year he was appointed a surgeon on the staff by the inspector-general of hospitals, Mr Adair, and in the spring of the ensuing year he went to Belleisle with the army. He served, during the continuance of the war, as senior surgeon on the staff, when he acquired his knowledge of gun-shot wounds. He settled in London on his return to England; but finding that his half-pay and private practice could not support him, he taught practical anatomy and surgery for several winters. He built a house near Brompton, where he pursued the study of comparative anatomy with unabated ardour. He discovered the changes which animal and vegetable substances undergo in the stomach by the action of the gastric juice; the mode in which a bone retains its shape during its growth; and explained the process of exfoliation, by which a piece of dead bone is separated from the living.

On the 5th of February 1767, he was chosen a fellow of the Royal Society. In the year 1768 he became a member of the incorporation of surgeons, and in the following year was elected one of the surgeons of St George's Hospital, through the influence of his brother. He published his treatise on the natural history of the teeth in May 1771; and in July the same year he married Miss Home, daughter of Mr Home, surgeon to Burgoyne's regiment of light horse. His private practice and professional reputation advanced with rapidity after his marriage; and although his family increased, he devoted much of his time to the forming of his collection. He discovered the cause of failure in the cure of every case of hydrocele, and proposed a mode of operating in which that event may certainly be avoided. He ascertained that simple exposure to the air can neither produce nor increase inflammation; and he considered the blood as alive in its fluid state. He also discovered that the stomach after death is sometimes acted on and dissolved by the gastric juice, respecting which he communicated a paper to the Royal Society.

Comparative anatomy occupied the greater part of his time and attention, and he suffered no opportunity to escape him. He dissected the torpedo in 1773, and laid an account of its electrical organs before the Royal Society. A young elephant which had been presented to the queen having died, it was given to Dr Hunter, and afforded him an opportunity of examining the structure of that monstrous animal, as did also two others which died in the queen's menagerie. In the year 1774 he published an account, in the Philosophical Transactions, of certain receptacles of air in birds, communicating with the lungs, and lodged in the muscular parts and hollow bones of these animals. Several animals belonging to the species called *Gymnotus electricus* of Surinam having been brought alive to Britain in 1775, their electrical properties excited a considerable share of the publication, and Mr Hunter purchased many of them after they died, for the purpose of prosecuting his favourite experiments. He published an account of their electrical organs in the Philosophical Transactions for 1775; and in the same volume appeared his experiments on the power of animals and vegetables to produce heat.

Mr Hunter was appointed surgeon-extraordinary to his majesty in 1776, in the autumn of which year he became extremely ill, when both himself and his friends apprehended that his life was in danger; but he happily recovered so far as to be able to publish the second part of his treatise on the Teeth in 1778, which completed the subject; and in 1779 he published in the Philosophical Transactions his account of the Free Martin. He was chosen a fellow of the Royal Society of Sciences and Belles Lettres at Gottenburg, and in 1783 he became a member of the Royal Society of Medicine and the Royal Academy of Surgery in Paris. When Mr Adair died Mr Hunter was appointed inspector-general of hospitals, and surgeon-general to the army. This event happened in 1792, at which time he was elected honorary member of the Chirurgo-Physical Society of Edinburgh, and one of the vice-presidents of the Veterinary College of London, then first established. He published also three papers on the treatment of inflamed veins, on intro-susception, and on the mode of conveying food into the stomach in cases of paralysis of the œsophagus.

On the 16th of October 1793, when in his usual state of health, he went to St George's Hospital, and meeting with some things which irritated his mind, and not being perfectly master of the circumstances, he withheld his sentiments; in which state of restraint he went into the next room, and turning round to Dr Robertson, one of the physicians of the hospital, he gave a deep groan, and dropt down dead, being then in his sixty-fifth year, the same age at which his brother Dr Hunter had died.

HUNTER'S Isles, a cluster of small islands lying off the north-west extremity of Van Diemen's Land, and frequented by numerous sea-fowls and seals. Long. 145. E. Lat. 40. 30. S.

HUNTING.

Nature has prepared many advantages and pleasures for the use of mankind, and given them the taste to enjoy them, and the sagacity to improve them; but of all the out-of-door amusements that have occupied the modern world, at least the male part of it, nothing has better stood the test of time than the noble diversion of hunting.

> "Of all our fond diversions,
> A hunter's is the best;
> In spite of wars, and petty jars,
> That sport has stood the test."

And why has it stood the test? Not merely because the passion for the chase is interwoven closely with our nature; not because it originated in necessity, therefore originated in nature; but because it has been encouraged and approved of by the very best authorities, and practised by the greatest men. It cannot now, then, be supposed to dread criticism, or require support; neither can any solid objections be raised against a reasonable enjoyment of the sports of the field in general, provided what ought to be the pleasing relaxation of a man's leisure hours be not converted into the whole business of his life. But hunting, above all others, is a taste characteristically manly and appropriate to the gentlemen of Great Britain; and it has likewise another advantage over all other sports of the field, which adds much to its value in this land of liberty, and especially in the present age: it is a kind of Saturnalian amusement, in which the privileges of rank and fortune are laid aside, the best man in the chase being he who rides the best horse, and who is best skilled in the use he should make of his superiority.

But let us look a little into the origin of hunting, the encomiums passed upon it, and the advantages derived from it.

We shall commence with the sacred history itself, which describes the first warriors under the denomination of hunters; and not only did the passion for the chase form a kind of society between the dog, the horse, the falcon, and man, but Pliny is quite correct in saying that hunting was not only one of the first exercises of man, but that it gave rise to monarchical states. For example, Nimrod, *the first king*, who reigned at Babylon, devoted himself to hunting, and delivered his subjects from the savage beasts that desolated the country; and in the sequel, by making soldiers of his companions in the chase, employed them in extending his empire, and establishing his conquests. In fact, nothing in those days procured a man so much esteem as being an expert sportsman or hunter; and had not Nimrod been a sportsman, he would not have been a king. People submit themselves to government by force, as wild animals do, and not by choice; and he erected himself into a monarch by finding himself stronger than his neighbours. He taught the people to make up companies for *the chase;* and, after exercising them for this purpose in the first instance, he led them on by degrees to a social defence of one another, and thus laid the foundation of his authority and his kingdom. It is no wonder, then, that so many of the first kings or heroes of whom antiquity makes mention should be characterised as celebrated hunters, and destroyers of noxious animals; an employment prescribed in the Book of Moses, and deified in the theology of the Pagans. Bacchus is drawn by tigers, because he subdued them; Apollo obtained the laurels that encircle his brow, by killing the serpent Python; and Hercules got his lion's skin by his exploits in the forest of Nemæa. Diana was worshipped in her temple, the finest the world ever saw, in honour of her skill in destroying noxious animals; even Venus herself took the field, and Adonis was killed in the chase. The Egyptians, also, in their most splendid ages, were much addicted to hunting; and it was the common exercise of the children educated in the court of Sesostris.

But there would be no end to these examples of the acknowledged benefits of the chase, on the manners and characters of nations. The ancient Persians considered hunting not only as a serious employment, but an excellent preparation for war, in which the same weapons were used as in the chase; and their renowned monarch, Cyrus, was the first sportsman of his day. With the Athenians the passion for the sports of the field was so strong, that Solon was obliged to restrain the ardour for hunting, to prevent the people neglecting the mechanic arts, which it was his wish they should cultivate; and the Lacedemonians, who were warriors by profession, cultivated hunting with incessant care. It was not only their ruling passion, but there is reason to believe they exercised in it the greatest skill; and, as we learn from Virgil, in his third Georgic, they were celebrated for their breed of speedy dogs. But there is not a nation in which it has not been found necessary to restrain by laws the excessive love for the chase; so natural is it to man, and so apt to degenerate into a passion injurious both to health and to society.

One of the greatest compliments paid to the chase is, its having been considered as a theme worthy the pens of the ablest writers of the most refined periods of the world. Whilst Greece was the nursery and residence of every branch of polite literature, and of all the arts and sciences then known to mankind; whilst every study that depends on the powers of the imagination, or the faculties of the understanding, was there carried to the very summit of perfection; we find Xenophon composing his Κυνηγετικος, treating of every description of field-sports. He, according with the custom of the times, opens the subject with fable, and tells us that hunting, which he calls the gift of the gods, and the use of dogs, originated with Apollo and Diana, and that the invention was made a present of to Chiron, who took pupils in the art, each of whom was, in his turn, honoured by the gods (ἀπο θεων ἐτιμηθη). His real object, however, was to encourage in the youth of his country a taste for the pleasures of the chase, and other manly pastimes, as the best preparation for war, the senate, and the world. Whilst he condemns the effeminate man as shamefully useless to his country, he represents the well-trained sportsman as not only mighty in war, but ready to sacrifice his person and his wealth to the public good. As a preparation for war, and particularly the higher branches of the soldier's profession, we need not the testimony of Xenophon; for our own experience has shown us, that, speaking generally, no man takes a view of a country, at first sight, with equal facility to a sportsman, particularly a sportsman who has been accustomed to follow hounds. Indeed, unless he have what is called in the field, "a good eye to a country," he cannot ride with judgment after hounds in our enclosed or woodland districts; and when the chase is concluded, it is surprising to witness the rapidity with which an experienced fox-hunter sees the points of a country in which he is a stranger, that must lead him towards his wished-for home. With respect to the other advantages alluded to by Xenophon, he had very good authority for what he asserted of them. The

Olympic games were established by the Greeks for two distinct purposes: first, to inspire their youth with a love of glory, as well as a taste for manly and invigorating exercises, conducive to contempt of danger, and coolness when exposed to it; and, secondly, with a view of drawing together the leading men of the different states of Greece, which gave them an opportunity of deliberating upon matters of general concern. As regarded the other various occupations of life which a gentleman is called upon to fulfil and do honour to, we may remark, that an irreproachable moral character was a necessary qualification for a competitor at those games or sports. Drawing something like a parallel here, then, we may add, that neither is a sportsman in our own country esteemed, how skilful soever he may be, if his character be tainted with fraud; and we are not unmindful of the advantages derived from the mixture of society in the hunting-field, or of the many valuable and lasting friendships that may be dated from accidental meetings by the cover's side. But Xenophon wrote in praise of hunting rather perhaps as a soldier than a philosopher, giving it as his opinion, that the exercise of the chase formed the best soldiers in the world; that it habituated men to cold, heat, and fatigue; that it kindled courage, elevated the soul, and invigorated the body; that it retarded the effects of age, and rendered the senses more acute; and, finally, that the pleasure it afforded was a sovereign remedy against all mental uneasiness; in which latter sentiment he is seconded by a modern author of celebrity, who says that "the chase fortifies the heart as well as the body." Nor is Xenophon the only eminent soldier or philosopher of his renowned country who has written in commendation of hunting. Aristotle wrote a treatise on field-sports, by order of Alexander the Great; and Polybius, one of the greatest soldiers of any age, relates that Maximus restored discipline in the Roman legions, by often exercising them in hunting; and he even goes so far as to celebrate one individual sportsman, Ptolemy Epiphanes, for his dexterity in killing a wild bull. Amongst the poets of Greece, Oppian distinguished himself highly by his poems on hunting. So excellent, indeed, were they considered by his emperor, that he is said to have presented him with a piece of gold for every verse they contained, and thus they acquired the honourable appellation of "the golden verses of Oppian." Several of the most splendid similes of Homer are taken from hounds in chase, and it is in the manly character of Achilles that we chiefly recognise him as his hero.

The Romans at one time discouraged hunting amongst the upper orders of society, from the fear of its becoming a passion which might divert them from their essential duties. But here they committed an error; for, aware of its beneficial effects in forming their people for war, they substituted public exhibitions of animals destroying each other in an amphitheatre, which could only have hardened the heart, without advantage to either body or mind. Yet we find many of their emperors encouraging hunting, and many of their best writers extolling it. The learned and polished Hadrian was so passionately addicted to hunting, and also to horses and dogs, that he erected monuments to the memory of the latter, and built a city on the spot on which he had killed a wild boar, after a desperate encounter with him, and which he called by a word which, being interpreted, signifies Hadrian's chase. Amongst the celebrated writers of the Augustan age, we may mention two, who, not being themselves sportsmen, could only have made sporting a subject for their pens, from a sense of the benefits arising from it. Virgil makes his young Ascanius a sportsman as soon as he is able to sit his horse; and he also makes him, at a very early age, the first in the fight (*primum bello*), as he had been the first in the field. In the speech addressed to him by the bold Numanus, which cost that hero his life, we have the finest contrast of the evils of effeminate habits with the benefits of manly pursuits, that the pen of a satirist could produce. The words, *O veræ Phrygiæ, neque enim Phryges!* "Oh, worse than women in the shape of men," convey the severest rebuke a nation could receive for having made themselves contemptible to their enemies, by the effects of an effeminate life, and pursuits unworthy of men; whereas the advantages of the manly exercises of youth are finely set forth in the vaunting exclamation of this hardy Rutulian. Neither is Horace behind his contemporary poet in his disgust of an effeminate youth. In the twenty-fourth ode of his third book, he beautifully contrasts those softening pleasures which emasculate the mind and enervate the body, with the opposite effects of manly sports and exercises; and, in his justly celebrated Epistle to Lollius, he recommends the chase, not only as a noble exercise, but as contributing to health and peace of mind. His *Carmen Sæculare* was also written in honour of manly exercises; and in another of his odes we find him upbraiding a young Roman for giving up the manly exercise of riding; and glancing at the destruction of Troy, and the feminine education of Achilles, seeming to insinuate, that effeminacy was likely to destroy the energies of his own countrymen, as it had those of others. That his apprehensions were not unfounded, a few centuries proved; for the Romans, after the conquest of Persia and other distant kingdoms, participating in their luxurious habits, became as easy a prey to the Goths and Vandals, as the Grecians and other nations had before been to themselves; and, in the decline of the republic, the few victories which they gained were achieved but by the terror of their name. Minor poets have also made sporting their theme. Gratius wrote a poem on coursing. He was contemporary with Ovid, and a sportsman, as the knowledge of his subject denotes. Nemesianus also, three centuries afterwards, wrote some poems on hunting, though they have not been so highly esteemed. But the sports of the field are alluded to by innumerable classic writers, and made the groundwork of their most beautiful allegories and fables, both in verse and prose; and perhaps, after all, the greatest compliment that can be paid to them, as well as the best answer to the assertion that any man can make a sportsman, is to be found in the latter department of literature. We allude to the letters of that accomplished country gentleman and scholar, Pliny the consul, in which he speaks of his prowess in the chase. In one addressed to Tacitus the historian, boasting of a famous day's sport he had been enjoying, he also boasts of the good effect it had had on his mind, telling him that Minerva accompanied Diana on the hills; and in the eighteenth letter of the fifth book he goes a point beyond this: "As for myself," says he to his friend Macer, "I am employed at my Tuscan villa in hunting and studying, sometimes alternately, and sometimes both together; *but I am not yet able to determine in which of those pursuits it is most difficult to succeed.*"

It is not surprising that hunting should have been the theme of poets, as poetry then ceases to be the language of fiction; neither can the subject itself be deemed unpoetical, as it affords an opportunity to expatiate, not merely on the beauties, but also on the endowments of nature. That the feelings of nature have more of rapture in them than those which are excited through the medium of science, is a fact which cannot, we think, be denied; and thus do we account for the exhilarating passion of the chase. To describe a chase, however, is a task of no small difficulty, and perhaps more so in prose than in verse, as the imagination must be powerfully excited by the transporting scenes on which it has dwelt, and cannot well be restrained in a mere recital of facts. When the noise of the battle is over, powerful must be the pen that could revive the clang of arms. "The chase is done," sings Ossian; "and nothing is heard on Ardven but the torrent's roar."

Somerville's poem of *The Chase* will live to the end of time; for although it was not faultless in the eyes of the perhaps too rigid Johnson, it is written with the spirit and fire his subject demanded; and many of the instructions it conveys, when stripped of their poetical dress, are esteemed by sportsmen of the present day. "Manners," says Lord Kames, "are never painted *to the life* by any one to whom they are not familiar;" neither could a man have written the poem we speak of unless he had been himself a sportsman. Indeed his descriptions of hunting the hare, the stag, and the fox, place the objects clearly and beautifully before our eyes, and show that the poet had often witnessed with rapture the scenes to which he devoted his muse. The following passage, descriptive of the feelings of a master of hounds on a hunting morning, is not merely truly natural, but at the same time highly poetical:

"Hail, gentle dawn! mild, blushing goddess, hail;
Rejoic'd I see thy purple mantle spread
O'er half the skies; gems pave thy radiant way,
And orient pearls from every shrub depend.
Farewell, Cleora! here, deep sunk in down,
Slumber secure, with happy dreams amused.
..............Me other joys invite;
The horn sonorous calls, the pack awak'd
Their matins chaunt, nor brook my long delay:
My courser hears their voice;—See there! with ears
And tail erect, neighing, he paws the ground:
Fierce rapture kindles in his redd'ning eyes,
And boils in ev'ry vein."

Although hunting *songs* are a species of ancient lyrics, of which the specimens are rare, and in our own country "the songs of the chase" do not appear to include any earlier than the middle of the seventeenth century, we have some of a more modern date that have been highly popular with the public, and no doubt have given the original impulse to many a good sportsman. The power and force of national songs have never been disputed in any age; and he who said, that if he were allowed to compose the ballads of a nation, he would soon alter its form of government, uttered a boast not altogether unfounded in the principles of human nature. Compositions of this kind, then, that tend to encourage a love of manly pursuits and pastimes, and give a relish to a country life, should by no means be thought lightly of by a people who, like ourselves, have ever been conspicuous for our excellence in the one, and our fondness for the other; but which, in the opinion of some, appear to be on the wane, as the natural consequence of our present state of almost excessive refinement. This would be a real cause for regret. The fondness for rural life amongst the higher order of the English has hitherto had a great and salutary effect upon the natural character of their country; and there cannot be found a finer race of men than the country gentlemen of Great Britain. Instead of the softness and effeminacy which characterise the men of rank of most other nations, they exhibit a union of *natural* elegance and strength, a robustness of frame and freshness of complexion, which are to be attributed to their living so much in the open air, and pursuing so eagerly the invigorating recreations of a country life. Their hard exercise produces a healthy tone of mind and spirits, as well as of body, accompanied with a manliness and simplicity of manners, which even the follies of a town cannot easily pervert, and can never entirely destroy. Let us, however, hope that the fears on this head are groundless; let us hope that what Horace sighed for, what Cato, Plato, and Cicero recommended, what Bion eulogised, what all the best poets of antiquity sang the praises of (according to the poets, the golden age was spent in the country), and for which kings and emperors quitted their thrones, will never be ill suited to, or considered as beneath the taste of a British country gentleman, in what circle soever he may move. That the sports of the field are classical, the authority of all ages will vouch for; neither is the man of fashion, or *haut ton*, by any means incompatible with the country gentleman and sportsman. On the contrary, how has the character of Paris been handed down to us by the poets? Was he not the finest gentleman, the greatest favourite of the female sex, the greatest beau of his day? Such he is represented to have been; but although a prince, he had been bred a shepherd; and from the robust habits he had acquired in his youth, he was the only man who could stand up against the powerful arm of Dares, the great champion of his day. What was the all-accomplished Pliny, or Lollius whose education Horace had superintended?

Again; on the score of health, the chief felicity of man, were it not for the sports of the field, the softness and effeminacy of modern manners, in the higher walks of life, would soon exhibit their pernicious effects on forthcoming generations, by depriving them of their natural defence against diseases incident to our climate, by subjecting them to that morbid debility and sensibility of the nervous system which lays the foundation of most diseases, as also depriving them of the courage to support them. And who enjoys the blessing of health equally with the country gentleman and sportsman? Somerville says,

"In vain malignant steams and winter fogs
Load the dull air, and hover round our coasts;
The huntsman, ever gay, robust, and bold,
Defies the noxious vapour, and confides
In this delightful exercise to raise
His drooping head, and cheer his heart with joy."

Certain is it, the rough sports of the country have been known not only to cure diseases of long standing in the human frame; but the exercise of hunting, *with the temperance it enjoins*, absolutely steels the constitution, as the poet expresses himself, against the attacks of the most common of the diseases peculiar to this variable climate. Its effect on the mind, which he also alludes to, is of no less value; for, from the very exhilarating nature of the amusement, it relieves it from dwelling upon its anxieties, from which few persons are free; and it is one of the best cures for the heartach, or any of those shocks which our flesh is heir to:—

"Dona cano divum, *lætas venantibus artes*,
Auspicio, Diana, tuo,"

sang the poet Gratius; and Horace's description of a sportsman's return to his family, after the toils and perils of the day, is a true picture of a country life, replete with every possible enjoyment.

Objections have been made to encouraging youth in a love of our national field-sports, on the score of their engrossing too much of their time and attention, to the neglect of more necessary attainments. "It is true," says a Roman historian, "the masters in every branch of learning, whom the accomplished father of Commodus provided for his son, were heard with inattention and disgust; whilst the lessons of the Parthian, or the Moor, in the arts of the javelin and the bow, could not be too often repeated." But where is the pursuit that may not be carried to excess? and yet without zeal no person ever succeeded in field-sports of any kind, much less in hunting. "Whatever thy hand findeth to do, do it with all thy might," said Solomon; and had not Providence implanted this zeal in man's nature, he never would have been what man now is, but, comparatively, a useless being. Objections are again made, that the sports of the field, hunting animals with dogs especially, are cruel; but the charge, if proved, does not altogether lie against man. The beasts and birds of the field have been given to him, as well as the way to procure them pointed out to him; or wherefore the almost unsearchable faculties of the dog? Some persons, however, have thought otherwise: "Is it a labour worthy of man," says a very celebrated English writer, "to watch from day to day, from night to night, the haunts of our fellow animals, that we may destroy them? To triumph over a poor mangled hare or hind, after we have harassed them up and down the country for many hours together with an army of dogs and men? Is it an exercise becoming the majesty of a rational spirit to run yawling with a parcel of hounds, perhaps a whole day together, after some timorous animal?" In answer to this it may be urged, that we knew no other method of availing ourselves of them when first they were given for our use; and it may be strongly urged, that the destruction of wild animals was never so speedily, and therefore humanely accomplished, as it is at the present day. A century or two ago, the fox lingered all night in a trap, and then too often was subjected to a lingering, if not an agonizing death. He is now killed by hounds, generally in a short time, if he cannot escape from what may be deemed his lawful pursuers. The buck in the forest of the king, or in the park of the nobleman, is now no longer hunted down by the slow but sure blood-hound, a race nearly extinct, but the unerring eye of the rifle-shot seals his doom on the spot. We agree with the poet, that

> "Poor is the triumph o'er the timid hare;"

but she was given for our use, and must be taken, as Esau took the venison, *by hunting her;* and here likewise is an improvement. A hundred years back she was trailed up to her form, the operation perhaps of an hour, with the terror-striking notes of the hounds all that time in her ear; and then pursued for at least two hours more, by animals with not half her speed, but with a power of following her by the foot, which it was nearly impossible to evade. At the present day she is whipped out of her form, twenty minutes generally deciding her fate; and, in consequence of her being now pursued in the forenoon, instead of, as before, just on her return from her walk, she escapes oftener than she is killed. Animals destined to fall by the gun are now nearly certain of meeting with instant death. In addition to the increased skill of our marksmen, the improved formation of the gun enables it to carry destruction with a much surer hand, owing to the force and precision with which it carries its shot. Thus, if the game be stricken, it is stricken to instant death, not wounded and mangled by weak, scattered shot. Another consideration presents itself in the discussion of this subject. Life is said to be "sweet;" but strip it of intellectual enjoyment, and its sweetness is very considerably abated. But we will go one step farther. The natural death of wild animals must generally be lingering, and often painful in the extreme; they have no relief to fly to, but perish as it were by inches. This being admitted, perhaps the hand that instantly deprives them of life may be deemed the hand of a friend.

An old English writer on field-sports thus forcibly, though somewhat boldly, expresses himself on the alleged cruelty of hunting the hare to death. "What can be a more convincing proof of God's infinite wisdom, or even of his indulgence to the sons of men, than the formation of this animal (the hare), which naturally flies from creatures she never beheld in her life, makes use of the most refined politics to escape their pursuits (although she cannot foresee whether they are the effects of love or anger), and yet is forced to leave behind her such particles of matter as betray her flight? Again, of how nice and curious a contexture must be the innumerable pores or pipes of the dog's nostrils, which serve as so many sheaths, or canals, to convey the said particles to the brains of the hounds, there to animate and put in motion every limb, joint, and muscle of their bodies. How excellent was the Hand that furnished these creatures with such tuneful notes to assemble their fellows, and give tidings to their masters, with such an amazing art to unravel the various windings of the fugitive, with so relentless fury to pursue her to the death."

But our sensibilities towards the sufferings of animals are limited, not only in wisdom, but in mercy (for, increase our sensibilities, and who could live?) and let us not charge a sportsman with cruelty because he is the destroyer of that part of the brute creation which was evidently intended should be destroyed by some one. Sportsmen have existed, and must for ever exist, from necessity. They have extirpated some animals, and culled out such as are serviceable to man, and submit to his will and government. Those that will submit are his friends, those that will not are his foes; and so it was intended to be since the charge was given to Adam, and the subsequent commission to Noah. The sports of the field, indeed, as now followed, are generally allowed to have a tendency to improve and promote a free and generous conduct, as well as that manly spirit which is the very reverse of cruelty; and, in the harmless exercise of our imagination, looking at that law of nature which enjoins the destruction of one animal for the good of another, so far from passing a hard sentence on the sportsman, we think with the poet, that

> "His life is pure, who wears no fouler stain!"

No great satisfaction would arise from a reference to the practices of the ancients in the field, who, it appears from Virgil, hunted any thing, from the wild ass to the stag; but, we have reason to believe, without much system, as far as their dogs had to do with it. We conceive the ancient Germans and Gauls to have been the best early sportsmen upon system; and the ancient Britons, who came originally from Gaul, and, according to Cæsar and Tacitus, were one of the widely-extended Celtic tribes, introduced, or rather brought with them from Gaul, that ardent passion for the chase for which Great Britain has ever since been remarkable. The Anglo-Norman and early English monarchs likewise all appear to have had a passion for the chase; and although a code of laws relative to hunting was formed by one of the Welsh princes in the twelfth century, containing a list of animals, climbing ones, for example, which does not accord with the present idea of *hunting*, we hear nothing of fox-hounds *per se*, till we find them in the kennel of Edward I., and an item in his wardrobe book of L.21. 6s. as the annual expenses of his pack, consisting of six couples. Soon after this period, at all events in the course of the next king's reign, the diversion of hunting in England may be said to have been first reduced to something like a science; treatises having been written on the subject for the instruction of young sportsmen, as well as rules laid down for the observation and conduct of those who filled the various offices, in the forest, the kennel, and the stable. One of the most curious of these performances, is a manuscript written in the beginning of the fourteenth century, in Norman French, by William Twice, huntsman to Edward II., an ancient translation of which occurs amongst the Cottonian manuscripts. In it are enumerated and described the different beasts that were then objects of the chase in England; and, in the manner of a dialogue, the huntsman is informed how he should blow his horn at the different points of a chase. But the generally rude system of hunting in the earlier days of England had previously been in some measure improved and amended by William the Conqueror, of whom Somerville thus writes:—

> "Victorious William to more decent rules
> Subdued our Saxon fathers; taught to speak
> The proper dialect; with horn and voice
> To cheer the busy hound, whose well-known cry

His list'ning peers approve with joint acclaim.
From him successive huntsmen learn'd to join
In bloody social leagues, the multitude
Dispers'd; to size, to sort, their warrior tribes,
To rear, feed, hunt, and discipline the pack."

Edward III. was a great stag-hunter; and even at the time he was engaged in war with France, and resident in that country, he had with him, attached to his army, sixty couples of stag-hounds, and an equal number of hare-hounds. We also learn from Froissart, that the Earl of Foix, a foreign nobleman, contemporary with King Edward, had one hundred and fifty couples of hounds in his castle. But it does not appear that the fox was much in esteem for the chase by any of the Anglo-Norman sportsmen; for in Twice's Treatise on the Craft of Hunting, he is classed last of all the beasts of venery, excepting the martern and the roe; nor does Somerville in his poem treat him with the respect that he pays to the stag or the hare. The first public notice of him occurs in the reign of Richard II., who gave permission, by charter, to the Abbot of Peterborough, to hunt him. Hunting, however, in all its branches, appears to have advanced steadily till the last century, when it flourished greatly by the encouragement given to it by George III.; and as time improves every art, it has at length, we believe, attained perfection.

Whatever pastime mankind indulge in, their first endeavour should be to make themselves acquainted with the best means of pursuing it, which will greatly increase the pleasure derived from it. But as the philosopher was laughed at for his offer of teaching Alexander the Great the art of war, so the theory of no pastime is worth any thing unless it be based on practice. And, perhaps, of all sports invented by reason for the use and amusement of mankind, there is none to which theory would avail so little as the noble and popular one of hunting. Indeed, the practical part of hunting, notwithstanding its popularity, is but little known, at least but little understood, from the perplexing difficulties that accompany it; and there is reason to believe it was still less understood before the appearance of a work, in which the whole system is minutely and accurately detailed by an eminent sportsman, and master of fox-hounds, of the early part of the last century. It is scarcely necessary to observe, that the work alluded to is "Beckford's Thoughts upon Hunting, in a series of familiar Letters to a Friend;" of which it has been said, "they are so truly the effusions of sound judgment, and so replete with the useful remarks of an experienced sportsman, that there is no room for any thing new or additional to be introduced upon the subject." It is true, this has been considered, and will continue to be considered, as a standard work amongst sportsmen; but as systems and habits change with time, and many of both have been materially changed since Beckford's day, another work on fox-hunting, also from a practical pen, made its appearance in 1826, and was well received by the sporting world, viz. "Observations on Fox-Hunting, and the Management of Hounds in the Kennel and the Field, by Colonel Cook," several years a master of fox-hounds; hunting various English counties, but principally the Rodings of Essex, celebrated for the stoutness of its foxes.

It is only within a very short space of time that sportsmen have been given to communicate their thoughts, or the result of their experience in the field, to the public, unless under fictitious signatures. In proof, however, of the benefit derived from such contributions to the stock of sporting *science*, if such a term will be allowed; and likewise in confirmation of what has been advanced on the subject of change of systems and habits that occurs in the course of time, we will make a few comments on the practices of one of the most conspicuous sportsmen England ever gave birth to, the celebrated Hugo Meynell, Esq. of Quorndon Hall, Leicestershire, and made partially known through the medium of a small pamphlet, entitled "The Meynellian Science, or Fox-Hunting upon System," by the late John Hawkes, Esq. a personal friend of Mr Meynell's. That Mr Meynell studied fox-hunting as a science, we believe no one will deny; and that his master-mind was quite equal to the task he imposed upon himself, is also an admitted fact; for he was a man of more than ordinary acuteness, coupled with a close and accurate observation of every thing that passed under his eye; and all this with the benefit of an education perfected beyond the usual extent of that bestowed upon, or, perhaps we may say, submitted to, by young gentlemen of large fortune in his day, having studied nearly three years under a private tutor after he became of age. That he shone beyond all others who had preceded him, in the breeding and management of hounds, is a fact universally admitted, producing, as Mr Hawkes says of them, "the steadiest, best, and handsomest pack of fox-hounds in the kingdom;" adding also the emphatic remark, that his object was to combine strength with beauty, and steadiness with high mettle. His idea of perfect shape was, short backs, open bosoms, straight legs, and compact feet; and the first qualities of hounds he considered to be fine noses and stout runners, opinions which all found to hold good.

But there were peculiarities in Mr Meynell's system of hunting, to which, as detailed by Mr Hawkes, we scarcely know how to reconcile ourselves. For example, he tells us that his young hounds were broken in to *hare* in the spring of the year, "to find out their propensities, which, when at all flagrant, they early discovered, and he drafted them according to their defects;" and in the same page he adds, "after hare-hunting, they were, the remaining part of summer, daily walked amongst riot." Now we cannot approve of entering hounds to an animal they are not intended to hunt, and are at a loss to comprehend what is here meant by the word "riot," unless it be hares (as the term generally implies) or deer (which were never found wild in his country), which they had been previously instructed to hunt. Their "propensities," also, by which is here generally understood their steadiness or unsteadiness, must, under such circumstances, have been rather difficult to pronounce an opinion upon, with the exception of their promising to be true to the line, and not given to skirt. The goodness or badness of nose could of course have been discernible when hunting their own game (the fox), to which, in our opinion, all fox-hounds should be entered. Beckford, we remember, speaks of his huntsman letting his puppies enter to a cat; but we cannot approve of such a practice.

Early in the autumn Mr Meynell hunted his woodlands, Charnwood Forest chiefly, with his whole pack, and then divided them into "the old" and "the young pack;" but, to show the disadvantage of this system, Mr Hawkes says, "the young hounds were hunted twice a week, as much in woodlands as possible, and in the most unpopular districts." The present plan of mixing young and old hounds together is far preferable to this, not only as they can then take their turn in the good and popular "districts," but, by having the assistance of older hounds in chase, the younger ones are less likely to do wrong.

Mr Meynell's idea of *perfection* in hounds, in chase, Mr Hawkes says, "consisted of their being true guiders in hard running, and close and patient hunters in a cold scent, together with stoutness." Their imperfections, "over-running the scent, and babbling, were considered their greatest faults." To all this every sportsman must assent.

The following passage contains perhaps rather more of enthusiasm than of fact, although a qualification is given to it in the concluding sentence. "Mr Meynell's hounds," says Mr Hawkes, "were criticised by himself and his friends in the most minute manner. Every hound had his peculiar talents, and was sure to have a fair opportunity of displaying them (!) Some had the remarkable faculty of finding a fox, which they would do, almost invariably, notwithstanding twenty or thirty couple were out in the same covert. Some had the propensity to hunt the doubles and short turns. Some were inclined to be hard runners. Some had a remarkable faculty of hunting the drag of a fox, which they would do very late in the day. And sometimes the hardest runners were the best hunters; and fortunate was the year when such excellencies prevailed."

"Mr Meynell," continues Mr Hawkes, "prided himself on the steadiness of his hounds, and their hunting through sheep and hares, which they did in a very superior manner. He seldom or never attempted to lift his hounds through sheep; and from habit, and the great flocks the hounds were accustomed to, they carried the scent on most correctly and expeditiously, much sooner than any lifting could accomplish." We are far from advocates for lifting hounds when it can be avoided; but knowing the so often insurmountable difficulties occasioned by flocks of sheep and herds of cattle in the country Mr Meynell hunted, in addition to a crowd of horsemen pressing upon the heels of the pack, we consider that, if, under such circumstances, hounds do not almost instantly recover the scent, the assistance of the huntsman is called for. The "steadiness and docility" of Mr Meynell's pack, we have reason to believe, were remarkable, and are vouched for by other authority than Mr Hawkes's. "A most extraordinary instance of discipline in hounds," says Colonel Cook (p. 202), "occurs to me, which I ought to have mentioned when speaking of that unrivalled sportsman the late Mr Meynell. He met in the Market Harborough (Leicestershire) country, at a small patch of gorse on the side of a hill, in a very large pasture field: the hounds feathered as they went in, and found instantly. The covert being only about two acres, and open, Mr Meynell immediately saw that the fox was in danger of being chopped; he therefore called out to Jack Raven, the huntsman, "Jack, take the hounds away;" and, at one of his usual *rates*, every hound stopped, and the pack were taken to the hedge side, when Mr Meynell called out three steady hounds, and threw them into the cover. The fox was so loath to break, that the three hounds kept hunting him for ten minutes, in the hearing of all the pack, who lay perfectly quiet at Raven's horse's feet, till the fox went away over the finest part of the country; and the moment Mr Meynell gave his most energetic, thrilling holloo (Mr Hawkes speaks of the power of Mr Meynell's cheering holloa, which, he says, "thrilled through the heart and nerve of every hearer"), every hound flew to him; the burst was the finest that any sportsman ever beheld, and after an hour and ten minutes they killed their fox." This is doubtless an astonishing instance of command of hounds with a scent before them, particularly so to those persons who are aware of the generally uncontrollable power of the impulse given to them by nature at that particular time; and were it not for the high reputation of the pack alluded to, we should, as we cannot doubt the fact, be inclined to say, it savoured a little of slackness, or, at all events, of a too severe discipline, bordering upon the annihilation of the distinguishing natural properties of the fox-hound, namely, high mettle and dash.

"Mr Meynell," adds Mr Hawkes, "was not fond of casting hounds; when once they were laid upon the line of scent, he left it to them; he only encouraged them to take pains, and kept aloof, so that the steam of the horses could not interfere with the scent. It is true, hounds should not be cast, if they can do the work themselves; and if the authority of Mr Meynell could restrain a Leicestershire field of horsemen to keep aloof when his hounds were at check, more time may have been given them to make their own cast; but it must be recollected that, when the hounds are at fault, the fox is not." Again, "when his hounds came to a check, every encouragement was given to them to recover the scent, without the huntsman getting amongst them, or whippers-in driving them about, which is the common practice of most packs. The hounds were holloa'd back to the place where they brought the scent, and encouraged to try round in their own way, which they generally did successfully, avoiding the time lost in the mistaken practice of casting hounds at the heels of the huntsman. When the hounds were cast, it was in two or three different lots, by Mr Meynell, his huntsman, and whipper-in; and not driven together in a body, like a flock of sheep. They were allowed to spread, and use their own sagacity, at a very gentle pace; and not hurried about in a blustering manner. It was Mr Meynell's opinion, that a great noise, and scolding of hounds, made them wild. Correcting them in a quiet way was the most judicious method. Whippers-in also should turn hounds quietly, and not call after them in a noisy, disagreeable manner." In all the foregoing remarks we coincide with the opinions of these two celebrated sportsmen. We think a huntsman should never be nearer than from sixty to a hundred yards of his hounds when they first check; nor can a whipper-in execute his office of turning or stopping a hound at this moment too quietly and discreetly; but no general line of conduct for either the one or the other can be laid down. Some hounds, and especially if they have been pressed upon by horsemen, will not turn to either horn or holloa, without a smack of the whip, or at all events a *rate;* nor will the body of the pack, if a little blown, or excited by a previous holloa, always try for their fox so well and *quickly* as they should do, if left quite to themselves; or, as Mr Hawkes so properly expresses himself, if left to "their own sagacity." That a great noise makes hounds wild no one doubts, and the system of holloaing is every year on the decrease. As for the division of the pack into three lots when at fault, that perhaps originated with Mr Meynell; indeed we believe it did; but the practice is now become not uncommon, of its being divided into two, namely, one lot with the huntsman, and the other with the first whipper-in.

"When hounds are going to the cry," writes Mr Hawkes, "they should be encouraged in a pleasant way; not driven and rated, as if discord was a necessary ingredient in the sport and music of a fine cry of hounds. Whippers-in are too apt to think their own importance and consequence consist in shouting, holloaing, and unnecessary activity. When hounds can hear the cry, they get together sooner than any whipper-in can drive them. If any hound is conceited, and disinclined to go to cry, he should immediately be drafted."

On the subject of blood, that is, killing and eating foxes, we entirely assent to the following remarks: "Blood was a thing Mr Meynell was more indifferent about than most masters of hounds. The wildest packs of hounds were known to kill the most foxes in cover, but very seldom showed good runs over a country. Hounds chopping foxes in cover is more a vice than a proof of their being good cover-hounds. Murdering foxes is a most absurd prodigality. Seasoned foxes are as necessary to sport as experienced hounds." Our own opinion of the value of blood to hounds perfectly accords with that which, it appears, was entertained by Mr Meynell; namely, that it is far from a *sine qua non* to the well-doing of fox-hounds, or any other hounds, as is apparent at once from the modern system of hunting the stag. If it be possible, the pack are not permitted to break his skin, much more to devour him; still, despite of the rating and flogging they get to prevent their injuring the object they are pursuing, they do pursue it to the last with all their might and main. But let it not be supposed that we set no value on what may be termed well-carried blood. On the contrary, we think the flesh and blood of a fox well found, and handsomely killed, by hounds in the moments of high excitement, must be very beneficial to them. But when chopped in a cover (generally the effect of accident, and not, as Mr Hawkes supposed, of vicious propensity in any individual hound), we consider a round of beef would be a more acceptable present to them; nor is the case much altered when a fox is digged out of an earth, after perhaps an hour's delay. We remember to have heard Mr Osbaldeston assert, that the best week's sport he ever had in Leicestershire when he hunted it, was after his hounds had been out nine days in succession without tasting a fox.

"Mr Meynell's natural taste," continues Mr Hawkes, "led him to admire large hounds; but his experience convinced him that small ones were generally the stoutest, soundest, and in every respect the most executive. His hounds had more good runs than any pack of his day. Two very extraordinary ones happened of a very rare description. One was a run of one hour and twenty minutes without a *check*, and killed their fox. The other was two hours and fifty minutes without a *cast*, and killed. The hounds in the first run kept well together, and only two horses performed it; the rest of the field were unequal to its fleetness. The other run alluded to was performed by the whole of the pack; and though all were up at the death, two or three slackened in their pace just at the last. One horse only went the whole of it."

Mr Hawkes thus speaks of the necessary qualifications of hounds to show sport:—"To obtain a good run, hounds should not only have good abilities, but they should be experienced, and well acquainted with each other. To guide a scent well over a country for a length of time, and through all the difficulties usually encountered, requires the best and most experienced abilities. A faulty hound, or injudicious rider, by one improper step, may defeat the most promising run." It is evident, from the above judicious observations, that an old-established pack of hounds must have great advantages over one of an opposite character.

We shall finish our extracts from this little pamphlet, which was merely circulated privately amongst the author's friends, but valued as from the pen of so eminent a sportsman as the late Mr Hawkes proved himself to be, both in the field and on the race-course, where he shone conspicuously as one of the best gentlemen-jockeys of his day, with his judicious remark on the conduct of sportsmen who follow hounds. "Gentlemen, and every person who makes hunting his pursuit," says he, "should learn to ride judiciously to hounds. It is a contemplative amusement; and much good diversion might be promoted by a few regular precautions. The principal thing to attend to is, not to ride too near the hounds, and always as much as possible anticipate a check. By which means the leading men will pull their horses up in time, and afford the hounds fair opportunity to keep the line of scent unbroken. Sheep, cattle, teams at plough, and arable land, are all causes of checks. Thoughtless sportsmen are apt to press too much on hounds, particularly down a road. Every one should consider that every check operates against the hounds, and that scent is of a fleeting nature, soon lost, never again to be recovered."

The following is the concluding paragraph, affording a good specimen of the writer's enthusiastic love of fox-hunting, as also of a cultivated mind:—"Fox-hunting," he asserts, "is a manly and fine exercise, affording health to the body, and matter and food for a contemplative mind. In no situation are the faculties of man more displayed. Fortitude, good sense, and collectiveness of mind, have a wide field for exercise; and a sensible sportsman would be a respectable character in any situation in life. The field is a most agreeable coffee-house, and there is more real society to be met with there than in any other situation of life. It links all classes together, from the peer to the peasant. It is the Englishman's peculiar privilege. It is not to be found in any other part of the globe, but in England's true land of liberty; and may it flourish to the end of time!"

There is perhaps no part of the material of fox-hunting more interesting than the management of hounds in the kennel, which, we do not hesitate in saying, presents one of the most curious scenes that are anywhere displayed in the whole circle of the transactions of mankind with the inferior animal creation. To see sixty couples of those animals, all hungry as tigers, standing aloof in their yard (as is the practice in some kennels), and, without even hearing, much less feeling, the whip, not daring to move until the order is given to them to move. And what is the order given? why, at the words, "Come over, *Bitches*," or, "Come over, *Dogs*," every hound of each individual sex comes forward, as the sex it belongs to may be called for, leaving those of the other sex in their places. Then the act of drawing them to the feeding troughs is an exceedingly interesting sight. Often, with the door wide open, and the savoury meat in their view, the huntsman has no use for his whip, having nothing to do but to call each hound by his name, which of course he readily answers to. The expression of countenance, too, at this time, is well worthy of notice; and that of earnest solicitation, of entreaty, we might almost say of importunity, cannot be more forcibly displayed than in the face of a hungry hound awaiting his turn to be drawn. He appears absolutely to watch the lips of the huntsman, anticipating his own name. A view of a pack of fox-hounds likewise in their lodging-rooms, is a most agreeable sight to those who love to see animals in a high state of enjoyment, which no doubt hounds are when reposing on their well littered-down benches after a hard day's work, and with their bellies well filled. They absolutely appear to feel for each other's comforts, in placing themselves in situations that enable their fellow-creatures to repose parts of their bodies upon their own, to render their position for sleep and rest more agreeable to them.

The system of fox-hunting has been much changed since that sport commenced. Almost all foxes were once found by the drag, and the first challenge was loudly cheered in days when the game was scarce. A long drag, however, although a great test of *nose*, is by no means desirable, as, if it happens to be down wind, the fox takes the hint, and is off long before the hounds can hunt up to his kennel. It was nevertheless a fine feature in the sport, as the gradual increase of cry, the cheering holloas of the sportsmen, and the crash when the fox was unkennelled, contributed greatly to ennoble the scene, and created, as it were, two climaxes in a chase, when it ended in blood. But another disadvantage attended it. Hounds could not be depended upon, taking the average of scent, to hunt a drag that had become cold; so they were obliged to be out very early in the morning, which was not only disagreeable, as encroaching upon the sportsman's rest, but was coupled with the disadvantage, at all events with the risk, of finding a gorged fox, too full to run far, much less to run fast. The modern system does not require the drag, as woodland covers are comparatively small to what they used to be; gorse covers made for the purpose of holding foxes are easily accessible to hounds accustomed to draw them; and the game is in most countries so plentiful, that if a fox be not found in one cover, he is almost certain to be found in another, and that not far off. The consequence is, no more time is now lost in drawing two or three gorse covers, than the drag of one fox formerly occupied; neither did that always lead to a find. Moreover, at the present hour of finding, there is but little chance of unkennelling a gorged fox.

It is by some asserted, that what are called woodland foxes are stouter runners than those bred in the artificial gorse and other covers, and we have good reason to believe they are so. But the great objection to large woodlands is the uncertainty of getting a run, from the difficulty of making foxes break from them, as they naturally hang to places which appear to afford them security; and it often happens that hounds, and the horses of the servants, have done a fair day's work before the run begins. On the other hand, we admit that a fox found in a wood of considerable extent is more likely to show a decidedly good day's sport, than one found in an artificial cover, and for this reason: he slips away unperceived, eight times out of ten, and consequently has time to look about him, and make his points, ere the chase commences; whereas a fox viewed away from a small gorse cover, within sight of a hundred or two of horsemen, is bullied, frightened, and soon blown, which occasions him to run short; and, of course, if the scent serves, and the hounds are good, he cannot live long, half an hour being as much as can be calculated upon under such circumstances. Gorse covers, however, if not too small,—not under three or four acres,—are indispensable in a hunting country, as foxes are very fond of them for their security against any thing but fox-hounds; and another great advantage attending them is, that they can be placed wherever it may be thought desirable to place them.

The making of gorse covers requires no small attention, we had nearly said *skill*. The ground is all the better for being trenched to the depth of from a foot to a foot and a half, and it should be made as clean and in as good condition as if it were to be the seed-bed of turnips. The seed should be minutely examined, as it often fails from having lost its germinating properties; and it should be drilled in the ground, and hoed, after the manner of a turnip crop. By keeping it clean by the hoe, it will, if the seed be good, *and the land dry*, often hold a fox in the second year, but will seldom fail in the third. Some writers, Colonel Cook among the number, speak of broom being sown amongst gorse. This should never be, as all huntsmen who draw, or run through, broom covers, can vouch for their being decidedly inimical to scent. A novel description of fox-cover came into fashion a few years back in Leicestershire, but is not highly approved of, from the difficulty hounds experience in drawing it. Strong black thorn stakes are driven into the ground endways, at a small distance apart, and the rank grass and weeds growing rapidly over, and entwining with them, form a strong cover the first year; and it is found proof against a fall of snow, which gorse covers are not, and are often forsaken by foxes on that account. All artificially-made covers should be not nearer than half a mile at the least to any house or village; and if on a gently sloping bank, facing the south, foxes will like them better.

Some sportsmen object to many rides being cut through covers, as they are so often the cause of foxes being headed by the horsemen. The objection in part holds good; but a certain number of rides are necessary in all large covers, to enable the servants to get near their hounds, who might otherwise be disposed to run riot, as they soon discover when they are out of the reach of either rate or whip. Woodlands, with rides in them, are essential to the making of young hounds in all countries; and the finest in England are those of the Duke of Buccleuch, near Kettering in Northamptonshire, within the limits of the Pytchley Hunt, with rides, or, speaking more properly, avenues in them, to the extent of upwards of fifty miles.

When speaking of the disadvantages of large woods, in which foxes are apt to hang or dwell, Colonel Cook recommends killing a fox, and letting the hounds eat him, in the middle of them; which we believe will generally have the desired effect. On the other hand, should a fox be killed in a small cover, he should, if possible, be carried out of it before the hounds break him up, for reasons which are obvious from the foregoing remark.

The arrangement of earths, and the stopping of them, are matters of no small importance in a hunting country. Artificial ones are sometimes made, but they are reckoned unhealthy for foxes; and the best are those made by badgers, which can always be commanded at pleasure, by turning out those animals in pairs. On the proper and careful stopping of earths every thing depends; for nothing can be more annoying to sportsmen than to have their fox get to ground, just as the hounds have well settled to the scent of him, with every prospect of a run. There are various methods of stopping earths, but none more secure than by a bunch of gorse, or furze, crammed well into the mouth of them, with the stalks pushed inwards. When earths are only slightly stopped, a fox will scratch his way into them; and as this very often happens, it shows the necessity of a careful and experienced earth-stopper; and we agree with Colonel Cook in thinking it better to pay for each day's stopping, rather than annually in the lump, reserving the power to withhold payment in case of evident neglect. The expense of earth-stopping varies according to the nature of the soil, covers, &c.; but in certain countries it amounts to as much as L.200 per annum. It may also surprise some persons to hear, that the rent paid for artificial covers, that is, for the land on which they are made, in one hunt alone, in Leicestershire, amounts to upwards of L.700 per annum.

The following calculations of the expenses of a pack of fox-hounds, varying, of course, with the extent of them, are given by Colonel Cook, and admitted to be very near the mark; making allowance for the difference in the price of markets at the time he made them, and at others.

For hounds hunting twice a week:—

Six horses, including groom and helpers	L.300
Hounds' food, for 25 couples	150
Firing	30
Taxes	80
Whipper-in and feeder	140
Earth-stopping	50
Saddlery	40
Farriery, shoeing, medicine, &c.	50
Young hounds purchased, and expenses at walks	60
Casualties	100
	L.1000
A second whipper-in, and two horses in addition	170
	L.1170

Expenses for three times a week:—

Twelve horses, groom, helpers, &c.	L.600
Food for forty couples of hounds	220
Firing	40
Taxes	100
Two whippers-in and feeder	210
Earth-stopping	65
Saddlery	80
Farriery, shoeing, &c.	80
Young hounds purchased, and expenses at walks	80
Casualties	150
	L.1625

Expenses for four times a week:—

Fourteen horses, &c.	L.700
Hounds' food for fifty couples	275
Firing	50
Taxes	120
Two whippers-in and feeder	210
Earth-stopping	80
Saddlery	100
Farriery, shoeing, &c	100
Expenses of greyhounds purchased, and at walks	100
Casualties	200
	L.1935

"If you do not attend to the kennel department yourself," adds the Colonel, "but keep a huntsman, the expense will be at least L.300 more."

The only remark we have to offer on the foregoing calculations is, that the author does not allow a sufficient number of hounds for the several days' hunting in the week. For example, we venture to say, that no country could be hunted four times a week with fifty couples of hounds; at all events, fifty couples of hounds equal to that work are very rarely to be found. We agree with the writer, that either four times a week, or even twice, are preferable to three, for keeping hounds in regular work, when sound But on the subject of expenses we have a word or two more to say. Knowing, as we do, that they generally, we believe we may add always, exceed the calculations made by Colonel Cook, and in some instances by double, we consider it rather inconceivable that, in the present depressed state of land property, either noblemen or private gentlemen should be expected or permitted to bear all the charge of hunting a country themselves, knowing, as we do, the great sacrifices of property and income that have already been made to a perseverance in keeping fox-hounds, unassisted by a subscription. But this cannot go on much longer; nor indeed is it, with some exceptions, fit that it should; and, in support of our assertions, we will quote the sentiments of a writer on this subject, admirably well expressed, in a late number of the New Sporting Magazine.[1]

After hinting at the probable decline of a sport, from this cause alone, which Mr Burke described as "one of the balances of the constitution," he thus proceeds:—"As to the total abolition of the sport, we anticipate no such event. It is the favourite sport of Englishmen; and that which a man likes best he will relinquish last. Still, with the exception of countries that boast their Clevelands, their Yarboroughs and Suttons, their Graftons, Beauforts, Rutlands, Fitzwilliams, Segraves, Middletons (his lordship is since dead), and Harewoods—their great and sporting noblemen, in fact—we feel assured that, unless something be speedily arranged, half the packs in England must either be curtailed of their fair proportion of sport, or abolished altogether. This is not as it should be. Men are as fond of hunting, at least of riding to hounds, as ever; but though we feel that we may be telling a disagreeable truth to many, the fact is, that most men want to hunt for nothing. The day for this, however, is fast drawing to a close. The breed of country gentlemen who keep hounds—the Ralph Lambtons, the Farquharsons, the Assheton Smiths, the Villebois and Osbaldestons—are fast disappearing, in all probability never to be renewed. True that it is a fine, a proud sight, to see an English country gentleman spending his income on his native soil, and affording happiness and amusement to his neighbours, receiving their respect and esteem in return; but we cannot help feeling, that unless a man has one of those overwhelming incomes that are more frequently read of than enjoyed, it is hardly fair that the expenses of a sport which affords health and recreation to hundreds should fall upon his individual shoulders. Heirs at law will not be hindered by the remoteness of relationship from impugning the conduct of their ancestors; nor will it be any consolation to a son, on coming into possession of an overburdened estate, to know that the difficulties which oppress him were incurred for the purpose of keeping a pack of fox-hounds, by which his father afforded amusement to the country." It may here be not unappropriately added, that at the time the above was written (February 1834), three of the best hunting countries in England were vacant, viz. the Quorndon in Leicestershire, the Pytchley in Northamptonshire, and the Oakley in Bedfordshire.

Fox-hunting is a sort of prescriptive right, which England has claimed from a very early period; and, more than this, it has long been considered that the common law allowed persons to enter the lands of another in pursuit of a fox, the destruction of which was presumed to be a public benefit. This opinion was founded on the celebrated case Grundy *v.* Feltham (1, *Term. Reports*, p. 334); but in that of Earl of Essex *v.* Capel, Summer Assizes, 1809, the legality of hunting foxes over the land of another is rendered very questionable. This being the case, it is a great compliment to the sport, as no doubt injury of land to a certain amount, though small, is occasioned by it, that it is permitted to the extent to which we see it, in every county in Great Britain; and that an action of trespass is an unusual occurrence, must be considered as still more creditable to the yeomanry and tenantry who live by the occupation of land. On the other hand, however, it must be remembered, that the produce of land is very considerably enhanced by the great demand, as well as extra prices given, for hay, corn, and straw, as likewise by the encouragement to breeding horses; and that, wherever there is a colony of fox-hunters, it is accompanied by a great influx of money, which is expended in the immediate neighbourhood.

There were formerly three established classes of hunting in Great Britain, each of which had advocates, as it may have been suitable to situation, fortune, time of life, &c.; and although the struggle for superiority has ended in favour of that of the fox, we have reason to believe, that since what are termed "*packs of hounds*" have been established, hunting the stag or buck claims precedence of the hare; the hare of the fox; the otter, perhaps, of all. We will then offer a few more remarks upon them, as we have ranked them here.

Since the stag has ceased to be drawn for, and found in his native majesty, and hunted as a wild animal, "stag hunting" has lost all its interest with the sportsman; and when we say that the chase of no other animal is, after all, from first to last, so full of interest as that of the stag, the sportsman has some cause for regret. But wild-stag hunting could not have remained one of the popular diversions of Great Britain, for two sufficient reasons. First, from the country being so generally cleared of wood, there would have been a great scarcity of game; and, secondly, from the circumstance of the stag being, by his nature, unfit to be hunted during some of the months that sportsmen like to be on the field. The act of harbouring the deer, however, must be considered as amongst the very highest branches of the sportsman's art, and one which none but a well-practised sportsman could perform. Neither was the hunting to death of the wild stag by any means so easy a task as might be supposed, from the bulk of the animal, which it must be proportionally difficult for him to conceal. On the contrary, like the harts of Meandros, flying from the terrible cry of Diana's hounds, the "wise hart," or *cerf sage* as he is termed in ancient hunting, knows how to foil hounds perhaps as well as, or better than, most other wild animals, and is allowed to consult the wind in his course more than any of them. It is also said of him, that he will, when pursued, rouse other deer from their lair, to induce the hounds to run counter, or change; and his device of taking soil, with nothing but the nose to be seen above the water; running down a stream, and seeking for a hard and dry road when pressed; are facts too well established to require comment. But, after all, the subtilty of man in harbouring a deer, and knowing beforehand its age, sex, and size, by the slot and other distinguishing marks which it leaves behind it as it traverses its native forests, is more conspicuously displayed than in any other department of the chase, and is a most satisfactory illustration of "the dominion given to man over every living thing that moveth upon the earth." We shall then dismiss this part of our subject with the remark, that although, properly speaking, the diversion of hunting the stag is totally extinct in Great Britain, we can vouch practically for the fact, that there is not a nobler sight in nature than that of a full-headed stag roused from his lair by hounds, and majestically trotting before them, snuffing the air as he goes, and appearing to care little for his pursuers, from confidence in his natural powers. That these powers are great, all modern stag-hunters are satisfied of; and those of endurance, when chased, are allegorized in the fable of the Mænalæan stag, the running down of which is said to have occupied Hercules for a year, and was in consequence counted amongst the labours of that hero. That deer are superiorly winded animals, is apparent by the immense height they can leap, just before they die from bodily exhaustion; and it may be accounted for by their being furnished with *two* spiracles, or breathing places, one at the corner of each eye. Oppian, the Greek poet, must have supposed, by the following line, that they had *four*.

---

[1] No. xxxiv. vol. vi.

"Τετραδυμοί ῥινες, πισυρες πνοιησι διαυλοι,"

which was a mistake of the sporting bard; and some writers have made Aristotle say, that goats breathed at their ears, whereas he directly asserts the contrary. The classic writers, however, as well as our own poets, have taken some of their most beautiful similes from the chase of the deer; for example, Virgil's comparing the flight of Turnus to a stag trying to escape from the toils; and the death of the favourite hind by the hand of the young Iulus, a master-piece of pastoral poetry. But the death of the stag has been a favourite theme of our own poets; and both Shakspeare and Thomson have been equally happy in their description of the last moments of the antlered monarch of the forest, the latter particularly:

............................"He stands at bay,
And puts his last weak refuge in despair.
The big round tears run down his dappled face:
He groans in anguish; whilst the growling pack,
Blood-happy, hang at his fair jutting chest,
And mark his beauteous chequer'd sides with gore."

The following account of hunting the wild stag in Devonshire, but now nowhere to be seen in England, is from one of Nimrod's Tours, in 1824:—"The amusement of stag-hunting appears to be of ancient date in the county of Devon. For many years previous to 1775, the North Devon stag-hounds were kept in a style almost amounting to magnificent, by the then Sir Thomas Acland, Bart., when Colonel Basset took them and kept them to the year 1784. At that period the late Sir Thomas Acland became master of them, and kept them to the year 1793, when Colonel Basset took them again, at his own expense, and hunted them to the year 1801 inclusive; when ill health obliging him to part with them, he gave away all but six couples and a half to Lord Soudes. In 1802 Lord Fortescue revived them, by receiving from Colonel Basset the six couples and a half he had reserved, and kept them for that year. In 1803 they were first kept by subscription by Mr Worth, who continued at the head of them till 1810. In 1811 Lord Graves became master of them, also by subscription; but in the spring of 1812 Lord Fortescue determined upon keeping them at his own expense, which he did for seven years, when they were once more established by subscription; and since the year 1819 have been managed by Mr Lucas, who still continues at their head."

The next year after Nimrod visited them, they were given up; but we give the extracts from his account of two days' diversion with these hounds, on each of which they found a "warrantable" deer. Speaking of the first, he says, "When we arrived within half a mile of the covert in which a stag was harboured, the hounds, till then in couples, were put into a stable, when the celebrated Joe Faulknor, one of the whippers-in, was despatched with two couples of old hounds, for the purpose of rousing the game. One of these, a hound called Leader, was shown to me as a sample of a perfect stag-hound; and they were both said to be so steady, and to know a rate so well, that they will stop if a wrong (not a warrantable) deer be found, and will draw again. It was some time after Joe had got his tufters into covert before we heard any thing but an accidental note from his melodious pipe, which is certainly pitched in the right key. During this interval of suspense, for, as the poet sings,

......................"The blood more stirs
To rouse a lion than to start a hare,"

a farmer rode up with a piece of a stick in his hand, which was cut to the size of a *slot* he had found in a neighbouring wood. On my measuring it by my hand, I found it to be four inches in length, which, exceeding the usual length, showed it to be the slot of an old and very large stag." He then proceeds to relate that the harboured stag was roused, but afforded very little sport, on account of the extreme badness of the weather, and total want of scent. Of the find on the second day he thus speaks:—"The stag lay 'close couched,' or he must have been found before. We stood on an eminence which overhung the covert, and therefore could command a view of it. A long silence had prevailed, and we began to wonder what had become of Joe and his tufters, when all on a sudden a holloa was heard, and a hound threw his tongue:

"The deep-mouthed blood-hound's heavy bay
Resounded up the rocky way;
And faint, from further distance borne,
Were heard the clanging hoof and horn."

The rouse, it seems, had taken place in a small covert, a short distance below us, and we could see a stag of noble size, with branching antlers, trotting majestically along in a small opening between two woods, apparently paying little attention to the old hounds behind him. Indeed, at one time, so far from verifying the words of a poet, that *pedibus timor addidit alas*, he very coolly broke into a walk, as much as to say, 'I value you not;' but the staunch old tufters getting nearer to his haunches, obliged him to quicken his pace; and, to the great joy of all present, he put his head straight for a moor twelve miles across." But this is a subject for poetry; and it is impossible to read even the foregoing short account of rousing the deer with hounds, without calling to our recollection the beautiful lines of the Scottish bard in the *Lady of the Lake*, so strictly true to nature:—

"The antlered monarch of the waste
Sprang from his heathery couch in haste;
But ere his fleet career he took,
The dew-drops from his flanks he shook;

Like crested leader proud and high,
Tossed his beamed frontlet to the sky;
A moment gazed adown the dale,
A moment snuffed the tainted gale;
A moment listen'd to the cry,
That thicken'd as the chase drew nigh;
Then, as the headmost foes appear'd,
With one brave bound the copse he clear'd,
And stretching forward free and far,
Sought the wild heaths of Uam-Var."

Nimrod relates a few incidents connected with this day's sport, peculiar to hunting the deer. "I had," says he, "in this run, an opportunity of witnessing a circumstance peculiar to stag-hunting, and that is, *hunting in water*. Our deer beat down a river for about half a mile, the hounds following him by scent, which we might wonder how they could avail themselves of in so chilling an element as a rapidly-flowing stream. This, I think, may be called one of the master-pieces of natural instinct." Again, "Our stag once sank in Bremridge Wood, when he was fresh found; and the crash of those deep-tongued hounds at the time was very fine indeed. I was in hopes we should have viewed him in Castle Hill Park, but we were just too late. When he broke out of the park, he took a ring through some of the neighbouring coverts; when skirting it again, he returned to the place where he was found, and was killed at Bragford, a short distance beyond. He was once what is called 'set up' in the water, where he sank; but breaking out again, he was pulled down by the pack; and when one of the field went up to him to cut his throat, his eye was glazed. He was as fine a stag as ever was seen. He had brow, bay, tray, three on top on one horn, and two on the other; *and the weight of his haunch was thirty-nine pounds*." Nimrod laments the want of the French horns that formed part of this establishment, but which, some time before his visiting it, were done away with. The *recheat* and the *mort* were wanting to make the thing complete.

A kind of technological dictionary is required to almost all sports of flood and field. Of the technical terms in deer-hunting Nimrod thus speaks:—"What we fox-hunters call the ball or pad of a fox on foot, they term the 'slot.' We drag up to a fox; they draw on the slot, or walk up a deer. We find or unkennel a fox; they rouse or unharbour a deer. A fox runs up and down a cover; a dear beats up or down a covert, or a stream. With us, a fox is headed (turned back, or driven from his point); with them, a deer is blanched. We say, a fox stops or hangs in a cover, in a run; they say, their game sinks. We recover our fox; they fresh find their deer. We run into (kill) our fox; they set up the deer. The fox is worried; the deer is broken up. The fox goes a clicketting; the deer goes to rut. The fox barks; the stag bellows. The billiting (excrement) of the one is termed the feument or feumishing of the other. The brush of the fox is the single of the deer. The mask of the fox is the snout or nose of the deer. The view, the foil, the tally-ho, and who-whoop, are common, I believe, to all; but currant jelly and sweet sauce are not in the fox-hunter's vocabulary." "There are some expressions here," continues Nimrod, "which require farther explanation than I am able to afford them; and it is almost presumptuous in me, without any assistance at hand, to attempt giving an opinion on the subject. The word 'harbour,' however, is one of common acceptation, and implies a place of refuge. To unharbour a deer has long since been settled by Pliny: '*Excutere feram cubili.*' The expression is clear, and falls smoothly on the ear. Not so with 'taking soil:' it savours of filth, and is only applicable, in this sense, to a hog delighting, in the summer months, to wallow in mud or dirty water, previously to going to his bed. To 'beat up and down' is only another way of expressing to run to and fro, and is found in Terence, in the word *cursito*. The deer being 'set up,' can only be in allusion to his having his throat cut; for Cicero speaks of a man being 'set up' to have that pleasant operation performed:—'In cervicibus *imponere* dominum.' The stag roused from his lair has certainly a great superiority over unkennelling the fox. The latter is tame and puny, whereas the former is bold and classical, and quite in association with the wildness of the forest, of which this animal is the monarch. The lair is but another word for the den; as we read in Virgil's celebrated contrast of a town and country life, in which he so beautifully describes the manly pursuits of the latter; and likewise in the hunting scene with Dido and Æneas. The word feument I never heard before, but conclude it is derived from the Greek word φυρμα, *recrementum*."

The following is Nimrod's description of a full-headed deer. "A perfect head, I find, consists of brow, bay, tray, and three on top of each horn; but some have brow, bay, tray, and five on each horn, though these are rare."

Of the powers of endurance of a deer before hounds, as also of his subtilty in foiling them, the same writer thus speaks: "When we reflect on the powers of a stag, and look at his qualities for speed, we cannot be surprised that, when not overladen with flesh, or a 'heavy deer,' as he is then called in Devonshire, he should afford some extraordinary chases. The following well-authenticated facts will speak to their powers of locomotion: 'When Sir Thomas Acland kept the hounds, a farmer in the neighbourhood of Holnicote House saw a stag one evening in his fields, with a particular spot on his side. The next morning he met this same stag running in great distress, with the hounds close at his haunches, and he soon afterwards sank before them. On his asking Sir Thomas where he had found him, he learnt that it was twenty-five miles, as the crow flies, from the place where he was killed. He must therefore have travelled that distance in the course of the previous night.'" Again, on the power of leaping, which we have already noticed, and particularly in allusion to their wind, when otherwise much distressed, we find the following remark: "On my return from hunting on the preceding Tuesday's hunting," says Nimrod, "I was shown a leap, in Lord Fortescue's park, which a hind had taken last season before this pack, after a long run, and not ten minutes before she sank before them. What makes it more extraordinary is, that, on being paunched, a calf was taken from her almost able to stand. The fence was a stone wall, with a rail on the top of it, not to be broken; and your readers may judge of its height from the following statement, having had no other means of measuring it: My own height is five feet nine inches; the horse I rode is fifteen hands two inches high; the top of the fence was upwards of two feet above the crown of my hat; and it was up a steep bank that she approached it. The stag we ran went up to this fence, but did not attempt to leap it."

The natural history of the stag will be given in due course; and we now dismiss the subject of stag-hunting with the remark that, although, from the adverse circumstances attending it in a country like Great Britain, so generally free from large tracts of woodlands, which the red deer delights in, and also so much intersected with streams, real stag-hunting can never be again reckoned amongst the popular diversions in England, a good substitute for it is found in the turning out deer before fox-hounds in the neighbourhood of the metropolis, which has the advantage of affording a certainty of something in the shape of a run, and frequently very long ones, to persons whose time is precious, as well as the opportunity of, in a great measure, selecting the country best suited to the habits and propensities of the game. There are a number of stag-hunting establishments in England, and there has been a royal establishment of this nature throughout several successive reigns. In that of George III. stag-hunting was in high repute amongst the nobility and gentry forming the court, as well as of others residing in its neighbourhood. Mr Beckford said little about it, because he knew little: the reason he himself gives; but the following expression in his book relating to it made a deep impression on fox-hunters, who reluctantly acknowledge its truth. "Could a fox-hound," says Mr Beckford, "distinguish a hunted fox, as the deer-hound does the deer that is blown, fox-hunting would be complete."

The roe-buck has partaken of the same respite from the chase as the wild red deer, although by the old laws of the forest he was not considered as venison until hunted; and, according to Cæsar, the Britons did not eat this animal at all. The fact is, the roe-buck runs so short, after the first ring, that he is said to hunt the hounds, instead of the hounds hunting him; an artifice by which he hopes to elude his pursuers, as, of course, it must produce a confusion of scents. Neither does his cunning end here. When closely pursued in a thick wood, he will bound to one side of a path by a sudden spring, and, lying close down upon his belly, permit the hounds to pass by him without offering to stir. But the beauty of form and elegance of motion of the "favourite roe," which Solomon has made an emblem of connubial attachment, ought to protect it from the chase, although they do not appear to have done so in the country in which Solomon wrote, as he recommends to the man who has engaged to be surety for his neighbour, to deliver himself "as a roe from the hand of the hunter, and as a bird from the hand of the fowler." There has been only one pack of roe-buck hounds kept in Great Britain, and that was by a gentleman of the name of Pleydell, of Whatcombe House, near Blandford, Dorsetshire, lately deceased, in whose covers these animals abounded, as they also do in various parts of Scotland.

Hunting the *otter* was a sport much thought of in England, and is of very early date, chiefly perhaps for the great value formerly set on fresh-water fish, previously to that of the sea being so generally available throughout the country as it has been within the last hundred years, and continues to be still more so. The system of hunting the otter is this: The sportsmen go on each side of the river, beating the banks and sedges with the hounds. If there be an otter near, his "seal" (foot) is soon traced on the shore; and, when found, he is attacked by the sportsmen with spears, when he "vents," that is, comes to the surface of the water to breathe. If he be not soon found by the river side, it is conjectured he is gone to "couch" inland, for he will occasionally go some distance from his river to feed. He is traced by the foot, as the deer is; and when found, and wounded in the water, he makes directly for the shore, where he maintains an obstinate defence. He bites most severely, and does not readily quit his hold; on the contrary, if he seizes a dog in the water, he will dive with him to the bottom of the river, and will never yield to him whilst he has life. This sport is still pursued in the few fenny and watery districts that now remain in England, and has for a long time been confined principally to those parts where, from local circumstances, the other more noble and exhilarating distinctions of the chase cannot be conveniently enjoyed. An attempt, however, has been recently made to revive it, by a celebrated Oxfordshire sportsman, Mr Peyton, only son of Sir Henry Peyton, Bart., of which attempt we subjoin an account, extracted from the *Oxford Journal.* By this, two facts are established; the one, that otter-hunting spiritedly pursued is not a tame diversion; and the other, that the charge against this animal of destroying young lambs and poultry, is not altogether unfounded.

"We have great pleasure in informing our readers, that a novelty in the sporting world, as far as relates to this county, has recently been introduced by that ardent and indefatigable sportsman, Mr Henry Peyton, namely, a pack of those rare animals, otter-hounds, with which he hunts the country in the neighbourhood of Bicester; so that these midnight marauders and inveterate enemies of the finny tribe, which are numerous in the Cherwell, and streams near Rousham and North Aston, will not repose as heretofore in uninterrupted security. Mr Peyton hunts the pack himself, assisted by a very powerful auxiliary in the person of Viscount Chetwynd. These gentlemen start with their otter spears ere the day breaks, and at half-past five in the morning they may be seen two or three times a week wending their way on foot along the banks of the river, in pursuit of the 'furry varmint.' The pack has had some very excellent runs, one of which continued a distance of twenty-five miles, having been found in the river Cherwell, near to Flights Mill, and hunted through all the turnings of that serpentine stream to his lodgings at Watereaton, where he took refuge amongst the old willows, and succeeded in baffling his pursuers; subsequently to which a capital day's sport was afforded at North Aston. The hounds found near the mill, and went away in the direction of Nell Bridge; but twisting into the Adderbury Brook, after a chase of about eight miles, he was come up with, when some hard fighting occurred, in which a small terrier, bred by Mr Peyton, greatly signalized himself, being much punished, as indeed were all the hounds, from the determined ferocity of the otter, which was ultimately speared by Mr Peyton. It turned out to be a fine bitch otter, weighing upwards of twenty pounds, and, from the appearance of the dugs, it was conjectured that some of her family were in the vicinity, and consequently the hounds were again laid on, and finally succeeded in killing four fine cubs, weighing on the average eleven pounds each. The farmers of the neighbourhood who were up at the death were quite overjoyed, and nothing would satisfy them but the immediate cutting up of one of the cubs 'à la reynard,' and a distribution of the pads, head, and body, amongst them. It is said that these amphibious fish-merchants, when suffering hunger by reason of a scarcity of fish, will boldly in the season carry away young lambs; so that the farmers, independently of their stream being pilfered of fish, often sustain a more substantial injury, and therefore are much gratified at the opportunity now afforded of in some degree thinning the numbers of these voracious gluttons."

The otter-hound is not a distinct kind of hound, the strong rough-haired harrier answering the purpose best, provided he will hunt a low scent, as the game shows no small sagacity, as well as circumspection, in guarding against assault from man or dog. In 1796, on the river Worse, near Bridgenorth, Shropshire, four otters were killed, one of which stood three, another four hours before the hounds; and in 1804 the otter-hounds of Mr Coleman of Leominster, Herefordshire, killed an otter in a mill pond, which is said to have weighed thirty-four pounds and a half; supposed to have been eight years old, and to have consumed a ton of fish or flesh annually, for the last five years. It will be observed, in the list of hounds, there are three more packs kept in England for the purpose of hunting the otter.

Hare-hunting claims precedence of fox-hunting in the sporting chronology of Great Britain, and we believe of all other countries, inasmuch as a hare has always been esteemed excellent eating, and a fox the rankest of carrion. We gather from Xenophon that it was practised before his day, and he wrote fully upon it above three centuries before Christ, both hounds and nets being then used in the pursuit. Neither can we marvel at hare-hunting being the favourite diversion in all nations given to sporting where the use of the horse in the field had not become common. But we will go a point farther than this, and assert, that how inferior soever may be the estimation in which hunting the hare is held in comparison with hunting the fox, no animal of the chase affords so much true hunting as she does, which was the opinion of the renowned Mr Beckford.

In our description of the modern harrier (see article HOUND), we have termed him the fox-hound in miniature; and we may apply the simile to hare-hunting, which now, as long as the chase lasts, greatly resembles fox-hunting, only on a minor scale. In the modern system, there is no tracking to the seat with the one, any more than dragging up to the kennel with the other; but both animals are now chiefly stumbled upon by accident, and instantly fly for their lives. With the system of hunting also has the kind of hound been altered; there being now no longer occasion for that nice distinction of scent which was wanting to be a match for the windings and doublings a hare was able to make in her course when hunted by the slow and fastidious southern hound, and which was essential to the finding her at all, in countries where hares were scarce, by the perplexing means of a very cold trail. In fact, we do not think we can better elucidate the gradual but great change that has taken place in this highly popular and ancient British diversion, than by the following extracts from a very old work upon sporting called the *Gentleman's Recreation*, published nearly two centuries back.

"Your large, tall, and big hounds," says the author, "called and known by the name of the deep-mouthed or southern-mouthed hounds, are heavy and slow, and fit for woodlands and hilly countreys; they are of deep mouths, and swift spenders; they are generally higher behind than before, with thick and short legs, and are generally great of body and head, and are most proper for such as delight to follow them on foot, as *stop-hunting*, as some call it; but by most it is termed 'hunting under the pole;' that is, they are brought to that exactness of command, that, in their hottest scent and fullest chase, if one but step before them, or hollow, or but hold up or throw before them the hunting pole, they will stop at an instant, and hunt in full cry after you at your own pace, until you give them encouragement by the word of command; which much adds to the length of the sport and pleasure of the hunters, so that a course oft-times lasts five or six hours.

"Opposite to the deep-mouthed or southern hound are the long and slender hounds called the fleet or northern hound, which are very swift, as not being of so heavy a body, nor hath such large ears: these will exercise your horses, and try their strength; they are proper for open, level, and champain countreys, where they may run in view and full speed; for they hunt more by the eye than the nose, and will run down the game in an hour, and sometimes in less; that is, *a hare;* but the fox will exercise them better and longer.

"Between these two extremes there are a middle sort of dogs, which partake of both their qualities, as to strength and swiftness, in a reasonable proportion; they are generally bred by crossing the strains, and are excellent in such countreys as are mixt, viz. some mountains, some enclosures, some plains, and some wood-lands; for they will run through thick and thin, neither need you help them over hedges, as you are often forced to do by others.

"A true right-shaped deep-mouthed hound should have a round thick head, wide nostrils, open and rising upwards, his ears large and thin, hanging lower than his chaps; the flews of his upper lips should be longer than those of his nether chaps; the chine of his back great and thick, strait and strong, and rather bending out than inclining in; his thighs well trussed; his haunches large; his fillets round and large; his tail or stern strong set on, waxing taperwise towards the top; his hair under his belly rough and long; his legs large and lean; his feet dry and hard, with strong claws and high knuckles. In the whole, he ought to be of so just a symmetry, that when he stands level you may not discern which is highest, his fore or hinder parts.

"For the northern or fleet hound, his head and nose ought to be slenderer and longer, his back broad, his belly gaunt, his joynts long, and his ears thicker and shorter; in a word, he is in all parts slighter made, and framed after the mould of a greyhound.

"By crossing these breeds as aforesaid, you may bring your kenel to such a composure as you think fit, every man's fancy being to be preferred; and you know the old saying,

> 'So many men, so many minds,
> So many hounds, so many kinds.'"

In proof of our assertion, that there is more of true hunting with harriers than with any other description of hounds, we shall point out a few of the difficulties which they have to overcome. In the first place, a hare, when found, generally describes a circle in her course, which is in itself not only more difficult to follow, but it naturally brings her upon her foil, which is the greatest trial for hounds. Secondly, the scent of the hare is weaker than that of any other animal we hunt; and, unlike some, it is always the worse the nearer she is to her end; which accounts for its being better, and lasting longer, when going to her seat, than when running. There is scarcely any scent from a hare until she is in motion; therefore hounds constantly draw over her; and, of course, according to the length of time she has been gone to her seat after feeding, will be the difficulty of hunting her by the trail. In fact, at the most distant part of her previous night or morning's walk, the most tender-nosed hound in a pack will be scarcely able to own the scent at all. But the grand puzzler of all is, when hounds get upon the counter trail, about the middle of a hare's work, and the scent lies so equal that it is most difficult to distinguish heel from chase. No such difficulty as this can occur in any other description of hunting, and can only be obviated by the skill and experience of the huntsman in his notice of the working of his hounds. But although this difficulty is alluded to by almost all writers on the chase, we know not where to look for directions to the huntsman at the critical moment. It is true, Mr Daniel, in his *Rural Sports*, says, "To find out this, see if your hounds challenge counter; if they double, and carry it on counter, they will soon signify their error by opening singly." We conceive there is some reason in this remark, but it will not always avail. Hounds, harriers in particular, are fond of a scent; and if they cannot carry it forward, they will turn and hunt it heel; and here it is that the judgment of a huntsman turns to account. One with a keen eye, and *a perfect knowledge of his hounds*, may be able to unravel this mystery perhaps six times out of ten; but it is in no man's power to be sure of doing it. His chief guide is in the cry of his pack at this time, which will slacken instead of getting fuller if the scent be heel, as the experience of old hounds adds to their natural instinct the faculty of judging whether it is leading them to their prey or from it.

The great perfection of modern harriers is the head they carry over a country, the result of the pains now taken in breeding them of the same size and character; whereas, upon the old system, which was all for *the pot*, the chief dependence was upon a few couples out of the whole pack, the rest being wheresoever they liked or were able to be in the chase. On the other hand, it may be said modern harriers have not the nose and patience of the old sort, which perhaps they have not; but what they may lose in those respects, they more than gain in another, viz. by being nearer to their game in chase, and, by pressing her, not allowing her to make more than half the work she was able to do when pursued by slow hounds. In fact, the want of speed, and tedious exactness, of the southern hound, rendered the warmest scent, after a short time, cold; which may be proved from the fact of an hour being the average time of killing a hare, in former days, with a good scent, and from three to four with what is called a "fair," a "holding," or a "half scent." For our own part, speaking as fox-hunters, yet abandoning all prejudices against a sport it is too much the fashion to hold cheap, we consider that, to any man who is a real lover of *hunting*, that is, of seeing hounds do their work, and do that work well, a twenty minutes burst over a good country, with a well-bred pack of harriers of the *present* stamp and fashion, affords a high treat. To see them to advantage, however, it should be over a country in which the fields are large, and the fences stone walls, like those of Oxfordshire or Gloucestershire; for harriers, being for the most part obliged to meuse, strong hedges prevent their carrying a head in chase, which is the chief beauty in all hunting.

Somerville has these appropriate lines on the adaptation of hounds to their game:—

> "A different hound for every chase
> Select with judgment; nor the timorous hare
> O'er matched, destroy; but leave that vile offence
> To the mean, murderous, coursing crew, intent on blood and spoil."

Harriers should not be too large, certainly not more than eighteen inches high, or, by their speed, and, if good withal, they will much overmatch their game; but in a good and open country there should never be less than from eighteen to twenty couples in the field. A strong pack not only adds to the respectability of the thing (at all events, a small one greatly detracts from it), but, in our opinion, more hounds are wanting to pursue an animal that runs short, than one which, like the fox, generally makes for a distant point. The opinion of Mr Beckford is in opposition to us here. He says, "the fewer hounds you have, the less you foil the ground, which you will find a great hindrance to your hunting;" but it must here be remarked, that in the preceding sentence, this eminent sportsman speaks of the difficulty of getting a strong pack of harriers to run well together; a difficulty which no doubt existed in his day, but is totally overcome in the best hare-hunting establishments of ours. Indeed, we once heard a sportsman declare, and he was a sportsman who had hunted in all the best countries in England, that he had never seen a chase quite complete from end to end, not a single hound being out of place, until he saw it with a pack of harriers over the Cotswold Hills.

The following passage from Beckford is worthy of his pen, and should be strictly observed by all masters of harriers:—"Harriers, to be good, must be kept to their own game. If you run fox with them, you spoil them. Hounds cannot be perfect unless used to one scent and to one style of hunting. Harriers run fox in so different a style from hare, that it is of great disservice to them when they return to hare again. It makes them wild, and teaches them to skirt. The high scent which a fox leaves, the straightness of his running, the eagerness of the pursuit, and the noise that generally accompanies it, all contribute to spoil a harrier." We conclude that the writer here alludes to hunting wild foxes, which is now very rarely done with a pack of harriers, at least in a country near to which fox-hounds are kept. No master of harriers would do it, who wishes his pack to be perfect; and there are other reasons for his not doing it, which it is unnecessary to mention. But the very best understanding now generally exists between masters of fox-hounds and masters of harriers; and it is a common practice of such of the latter as reside in a fox-hunting district, to await the publishing of the fox-hunting fixtures before they make their own.

The following hints may be useful in hunting the hare. First, respecting the hare herself; hares breed from February to the end of harvest, and are said to live seven years. The buck affords the best sport, particularly *in the spring*, when, after one or two rings, he often goes straight on end for several miles. Hence the proverb, "as wild as a March hare." Some persons pretend to distinguish the sex upon the seat; at all events, the head of the buck is shorter, the shoulders redder, and the ears redder, than those of a doe; he is also larger, and his hind parts are of a lighter colour. If the claws are smooth and sharp, and the ears tear easily, the hare is young.

The difficulty of finding a hare by the eye is well known. It is an art greatly facilitated by experience, although not one person in ten who attempts it succeeds in it. But here we recognize the Hand that furnished her with such means for her security; as, from the delicacy of her flesh, she is the prey of every carnivorous animal, and her means of defence are confined only to her flight. In going to her form, she consults the weather, especially the wind, lying always, when she can, with her head to face it. After harvest, hares are found in all situations; in stubble fields, hedgerows, woods, and brakes; but when the leaves fall, they prefer lying upon open ground, and particularly on a stale fallow, that is, one which has been some time ploughed; as likewise after frost, and towards the spring of the year. In furze, or gorse, they lie so close as to allow themselves nearly to be trodden upon, rather than quit their form. The down or upland-bred hare shows best sport; that bred in a wet, marshy district, the worst, although the scent from the latter may be the stronger. If a hare, when not viewed away, runs slowly at first, it is generally a sign that she is an old one, and likely to afford sport; but hares never run so well as when they do not know where they are. Thus, trapped hares, turned out before hounds, almost invariably run straight on end, and generally till they can run no longer; and they generally go straight in a fog.

The chase of the hare has been altered, and rendered less difficult in some degree, by the improvement of the hound used in it. In the first place, she is now so pressed by the pace at which she is hunted, that she has not time, when first started, to visit the works of the preceding night; nor is she, from the same cause, so likely to run her foil. But when making out her foil, hounds are now not let to puzzle over it as formerly, but, if it be not quickly done, are rated forward by a whipper-in, to make good the head; and if that do not succeed, to make it good round the fences. Formerly, when hounds were at fault, the cast was made in a small circle to begin with, and then their huntsman tried wide; whereas they now generally, and especially if the game is supposed to be not far before them, make a wide cast at first, and then contract the circle if the wide cast fails. There is reason in this; for if the hare is on, the wide cast will cross her; and if she is not, she has most likely squatted. The old system was, "avoid a view, if possible." The modern one rather encourages a view, but no holloaing; for as hares regulate their speed in great measure by the cry of hounds, they are less apt to have recourse to shifts when the cry bursts upon them at once. In fact, to suit the taste of the day, which is to have every thing that moves, fast, it was necessary that the greater part of the system of hunting the hare should be changed. It used to be insisted upon, that harriers should never be lifted as long as they can possibly carry a scent; and Beckford says, "a hare is not fairly hunted unless the pack be left almost entirely to themselves; that they should follow her every step she takes, as well over greasy fallows as through large flocks of sheep; nor should they be cast, but when nothing can be done without it." This may have been all very well when gentlemen followed hounds on foot, or were content to be some hours killing one hare; or for Mr Beckford himself, who (although he admits having bred an infinity of harriers before he could get a pack to please him) thought hare-hunting should be taken as a ride after breakfast, to get an appetite to dinner.

But we have reason to believe, if a master of harriers of the present day wished to show his pack to advantage, and could have a choice of a run to display them, he would say, "Give me twenty-five minutes *in all;* the first fifteen a severe burst; then a fault, well hit off; and the remaining ten without a turn." But, it may be asked, wherefore the fault? We reply, because, although the speed of well-bred harriers, for a certain time, if not quite equal to that of fox-hounds, is too much for most hares, as well as for most horses that follow them, yet, after that certain time, say fifteen minutes, wind and power begin to fail, and a short check is useful. Besides, the ability of a pack, in quickly recovering a fault, is more than a counterbalance to their coming to a fault at all, which, with a short-running animal, as the hare is, it is often difficult to avoid, nay, rather to be looked for indeed in every field.

The difference in the terms used in hare-hunting and fox-hunting is comprised in a few words:—Harriers are cast off, in the morning; fox-hounds throw off. The hare is found by the quest or trail; the fox by the drag. The hare is on her form or seat; the fox in his kennel. The young hare is a leveret; a fox a year old is a cub. The view holloa of the hare is, "Gone away;" of a fox, "Tallyho." The hare doubles in chase; the fox heads back, or is headed. The harrier is at fault; the fox-hound at check. The hare is pricked by the foot; the fox is balled or padded. The hare squats; the fox lies down, stops, or hangs in cover; the "who-whoop" signifies the death of each.

Our ideas of a complete pack of fox-hounds are very soon expressed. For four days' hunting in the week there should be not much less than sixty couples of working hounds; nor do we think more are necessary, as hounds, like horses, are always better and sounder when in regular work. For three days in the week, forty couples are enough. They should have at their head not only a huntsman, but also a master, each of whom knows his business, and one *clever* whipper-in, and another as clever as you can get him. It is not necessary, because it is not feasible, that they should all be good drawers of covers; but it is absolutely necessary to perfection that they should all get to work as soon as a fox is found, and prove themselves true on the line their game has gone. As to their being quite free from riot on all days, and on all occasions, the man is not yet born *who can say with truth,* "my hounds *never* run riot." Nature is seldom extinguished; and as Æsop's damsel, turned to a woman from a cat, behaved herself very well till the mouse appeared, so will hounds occasionally break away upon riot, particularly when out of sight of the servants, in large covers, or when disappointed by a long blank draw. We conceive a pack of fox-hounds entitled to be called "steady from riot," if they will bear being put to the following test:—If, when at fault for their fox, in the middle of a large field, a hare gets up in view, and not a hound stirs, nor attempts to break away after her; and this without a word being said to caution them. But it is in chase, with only a holding scent, that a pack of fox-hounds display their excellence. In such a case as this there must be checks; and it being ten to one against their fox running straight, because they cannot press him, now is the time to see them work. Do they carry a good head when the scent is a-head and serves them well? Are they cautious when it does not? And do they turn short when the game has turned right or left, or is gone back? Are they careful not to overrun the scent, and will they stand pressing to a certain degree by the horsemen? But having overrun it, do they stop directly, and make their own cast? Should that fail, do they come quickly to horn or holloa—to their huntsman's cast? Do they fling for a scent when their huntsman lifts them to points, and not attempt to *flash,* or break away, without a scent? When the scent serves well, do they not only carry a good head over a country, but, as their game is sinking, does the head become better? If they do all this, and have speed and stoutness withal, they are equal to any fox in any country, and are worth a thousand sovereigns to a sportsman.

The number of fox-hounds taken into the field depends chiefly upon country; more being required in that which is woodland, than for an open champaign, or for our enclosed grass districts, such as Leicestershire. Eighteen couples are generally considered as sufficient for the latter; and the strongest woodlands do not require more than from twenty-two to twenty-five couples; and we consider the latter the more common number, in the field, of any pack in any country.

The average speed of fox-hounds is estimated at ten miles, point blank, over a country, with a good scent, in one hour; that is to say, making allowance for deviations from the straight line, hounds seldom go more than ten miles, from point to point, in that space of time. Mr Beckford has a very judicious remark on this part of his subject. "That pack," he writes, "may be said to go the fastest that can run ten miles the soonest, notwithstanding the hounds separately may not run so fast as many others. A pack of hounds, considered in a collective body, go fast in proportion to the excellence of their noses and the head they carry; as that traveller gets soonest to his journey's end who stops least upon the road. Some hounds that I have hunted with would creep all through the same hole, though they might have leaped the hedge; and would follow one another in a string, as true as a team of cart-horses. I had rather see them, like the horses of the sun, *all abreast.*"

There is nothing in the history of our domestic sports and pastimes to inform us correctly as to the date of the first regularly-established pack of fox-hounds kept in England. Neither the holy prioress of St Alban's, Dame Juliana Bannes, Markham, nor any of the very old writers on such subjects, are able to satisfy us on this point; but, on the authority of the Rev. William Chafin, in his *Anecdotes respecting Cranbourn Chase,* the first real steady pack of fox-hounds established in the western part of England was by Thomas Fownes, Esq. of Stepleton, in Dorsetshire, about the year 1730. "They were," says the author, who wrote in 1818, "as handsome, and fully as complete in every respect, as the most celebrated packs of the present day. The owner, meeting with some worldly disappointments, was obliged to dispose of them; and they were sold to Mr Bowes, in Yorkshire, the father of the late Lady Strathmore, at an immense price for those days. They were taken into Yorkshire by their own attendants, and, after having been viewed and much admired in their kennel, a day was fixed for making trial of them in the field, to meet at a famous hare-cover near. When the huntsman came with his hounds in the morning, he discovered a great number of sportsmen, who were riding in the cover, and whipping the furzes as for a hare; he therefore halted, and informed Mr Bowes that he was unwilling to throw off his hounds until the gentlemen had retired, and ceased the slapping of whips, to which his hounds were not accustomed, and he would engage to find a fox in a few minutes, if there was one there. The gentlemen sportsmen having obeyed the orders given by Mr Bowes, the huntsman, taking the wind of the cover, threw off his hounds, which immediately began to feather, and soon got upon a drag into the cover, and up to the fox's kennel, which went off close before them, and, after a severe burst over a fine country, was killed, to the great satisfaction of the whole party. They then returned to the same cover, not one half of it having been drawn, and very soon found a second fox, exactly in the same manner as before, which broke cover immediately over the same fine country; but the chase was much longer; and, in course of it, the fox made its way into a nobleman's park, I believe Lord Darlington's, which was full of all sorts of riot, and it had been customary to stop the hounds before they could enter it, which the best-mounted sportsmen attempted to do, but in vain; the hounds topped the highest fences, ran through herds of deer and a number of hares, without taking the least notice of them; ran in to their fox, and killed him some miles beyond the park; and it was the unanimous opinion of the whole hunt that it was the finest run ever known in that country. An ample collection of field-money was made for the huntsman, much beyond his expectation; and he returned to Stepleton in better spirits than he left it, and told his story as above related, in which we must allow for some little exaggeration, very natural on such an occasion. This pack was probably the progenitors of the very fine ones now in the north. Before this pack was raised in Dorsetshire, the hounds which hunted in the chase hunted all the animals promiscuously, except the deer, from which they were necessarily made steady, otherwise they would not have been suffered to hunt at all in it." We have good reason to believe Lord Yarborough's fox-hounds, at Brocklesby Hall, Lincolnshire, were established as far back as the year 1700. The present huntsman and his late father hunted them more than fifty years.

The Fox.

The fox makes a conspicuous figure in the natural history of animals; still, in some respects, his character has been over-rated and exaggerated. He is a native of all temperate regions; and although we read of the cur, the greyhound, and the mastiff fox, we consider a fox as a fox, the difference in size, colour, &c. being dependent on either climate or food. It is true, they are larger in some particular parts of England than in others; and it is generally believed, that such as are what sportsmen call "stub-bred foxes," that is, bred above, and not below ground, are the largest. It is in this sole instance that the habits of the fox differ from those of the wolf, to whose genus he belongs; the she wolf never bringing forth her young, as the fox does, under ground. But although the general conformation of the fox is the same as that of the wolf, his external form has a greater resemblance to the dog, with whose character also he closely assimilates, when domesticated, in expressions of affection, of anger, or of fear. When minutely examined, and particularly in relation to his predatory life, and, consequently, the dangers to which he is exposed, he will be found to be abundantly endowed by nature with the instinctive faculties requisite for such a life, in addition to the most elegant form an animal of his size is capable of. Foxes copulate in the winter months, and of course bring forth in the spring, on an average perhaps half a dozen cubs at a litter, born blind like the dog; but the period of each depends on the mildness or severity of the winter. Excepting during the season of sexual desire, the fox is a solitary, not a gregarious animal, for the most part passing the day in sleep, and the night in prowling after food.

The food of the fox is extremely variable; indeed, very few things that have or have had life come amiss to him: but we have reason to believe that rabbits, hares, poultry, partridges, and pheasants, with their eggs, are his favourite repasts; and when these are not to be had, he contents himself with field-mice, black-beetles, snails, and frogs. That he can even exist solely on the latter, was proved a few years ago, by the circumstance of a fox-hound and a fox having been found at the bottom of a dry well, into which they had fallen; the hound had perished from hunger, but the fox had supported his life on frogs. Of those animals and birds which we call game they are without doubt destroyers—of pheasants, it is asserted, twenty-five per cent.; but how it happens that they have been charged with feeding on grapes, we are, as far as our own experience directs us, quite at a loss to determine. The fact, however, is stated by several accredited writers, and has given birth to the fable of the fox and the grapes, the moral of which is a severe rebuke to an envious person who "hates the excellence he cannot reach." Aristophanes, in his *Equites*, compares soldiers devastating a country to foxes destroying a vineyard; and Galen (*De Aliment.* lib. iii. c. 2) tells us, that hunters ate the flesh of foxes in autumn, because they were grown fat with feeding on grapes. There are also two lines in Theocritus (*Idyl.* E. v. 112) which admit of the following version:—

> I hate those brush-tailed foxes, that each night
> Spoil Micon's vineyards with their deadly bite.

He is likewise accused of eating human flesh, and, we have reason to believe, accused justly. In addition to the sentence pronounced by David, in the sixty-third psalm, that the enemies of God and himself should be "a portion for foxes," we have the following interesting historical anecdote. When the famous Messenian general Aristomenes was thrown into the Ceadas (a deep chasm into which criminals were hurled) by the Lacedæmonians, his life is said to have been preserved by following a fox that was feeding on a dead body, to the aperture at which he had entered, and through which, after enlarging it with his hands, he himself escaped.

But although the subtilty of the fox has been proverbial from the earliest times; so much so, that our Saviour himself called the tetrarch Herod "a fox," by way of signifying the refinement of his policy; we do not perceive that, with the exception of a timid prudence on breaking cover, he shows more sagacity in his endeavours to baffle his pursuers than the hare is known to do, if indeed so much. To "catch a weasel asleep," is a typical designation of an impossibility; but foxes are frequently surprised in their naps by hounds drawing upon them, up wind, particularly when gorged with food. In the faculty of natural instinct, however, they are vastly superior to hares, and equal in this respect to the dog; there being well-attested instances of their being sent, *marked*, upwards of fifty miles in a bag, and, having escaped being killed by hounds before which they were turned out, being retaken in their native woods. But it is in his last moments, when seized by hounds, that the superiority of character in the fox over the hare exhibits itself. He dies in silence; but he sells his life dearly; for, revengefully seizing upon the first hound that approaches him, he only relinquishes his hold with the last gasp.

When first the fox was hunted in Great Britain, he was considered merely as a beast of prey, and killed in any way in which he could be got at, generally by being caught in nets and pitfalls, or killed at earth by terriers; his scent not being considered favourable to hounds by our forefathers. Although they admitted it to be hotter at hand than that of the hare, their favourite object of pursuit, they believed it to be sooner dissipated; but perhaps the real cause of their objection was, in the general inequality of speed and endurance in the hounds of their days and a really wild fox; and foxes then were undoubtedly stouter, and able to run much greater distances from point to point, than they now do, when they have comparatively so short a distance to travel for their food, as well as being often over-fed. These animals, then, being always destroyed when an opportunity offered, were of course generally scarce; which, added to the great extent of woods and other fastnesses with which England then abounded, accounts for the fact of hunting the fox, unless as a beast of prey, not being in vogue until these objections were removed. But the fox was ever considered as a mischievous animal, and, in one signal instance, is said to have been made an engine of mischief to a vast extent, in carrying fire and flame into the standing corn of the rebellious Philistines. A solution of this account, however, on natural principles, being difficult, it is pretty generally admitted that a mistake in the translation has given rise to it.

As the preservation of the fox is now more an object in Great Britain than his destruction, it may not be amiss to observe, that a few links of an iron chain, such as an old plough-trace, or a small piece of red cloth, suspended near to the spot on which a hen-pheasant sits, is a certain protection from foxes, of herself, her eggs, or her brood.

It is asserted by sportsmen of experience, that the scent of foxes varies with the animal; and that a vixen fox which has laid up (brought forth) her cubs is nearly devoid of scent.

Huntsman.

In the lower ranks of life there are callings which require the exercise of skill and judgment to the very utmost of their extent; and we know of none that comes more directly within this class than that of a huntsman does, of whom it may be said, that in all his operations he has not only to exercise his mental faculties at every step he goes, when unravelling the intricacies of the chase, but actually to tread a path nearly unknown to human reason. *Fimus oratores, nascimur poetæ*, is a good definition of the constitutional qualifications of a first-rate poet, at all events of the difficulty of becoming one; and really when those of a huntsman are all summed up, if the life of man be not too short, years of toilsome labour appear to be scarcely sufficient to evince, even to a man of talent, a perfect knowledge of his art. Let us first hear what Beckford says of him, and then we will offer our own sentiments on the subject, which vary little from those entertained by this great authority on all matters of the chase. "A good huntsman," says he, "should be young, strong, and active, bold and enterprising; fond of the diversion, and indefatigable in the pursuit of it; he should be sensible and good tempered; he ought also to be sober; he should be exact, civil, and cleanly; he should be a good horseman, and a good groom; his voice should be strong and clear; and he should have an eye so quick as to perceive which of his hounds carries the scent, when all are running; and should have so excellent an ear, as always to distinguish the foremost hounds when he does not see them. He should be quiet, patient, and without conceit. He should let his hounds alone *when they can hunt*, and he should have genius to assist them *when they cannot*." It is scarcely necessary to observe, that Mr Beckford is here speaking of a huntsman to fox-hounds, his demands on the hare-hunter being somewhat more moderate; and yet the difficulties he has to combat with are more than obscurely acknowledged. Aware that practice is the key to excellence in every art, and that experience is the great mistress of all human knowledge, he requires age, with its experience, to fit the hare-huntsman for his office, and to be a match for the wiles of the hare; very ludicrously adding, that, "for patience, he should be a very Grizzle."

We do not think we exaggerate when we say, that the picture here drawn of a clever huntsman may, in one degree (of bodily endowments at least), be termed a near approach to human perfection; nor do we hesitate in adding our conviction, that if to the attributes here given him are joined a comprehensive mind and a humane heart, nothing is wanting to make it complete. As the chase is said to be the image of war, "but without its guilt," let us suppose Mr Beckford had been drawing the character of a soldier, and not a huntsman. Could he have given him higher qualifications than a clear head, nice observation, a good constitution, undaunted courage, a powerful voice, an accurate ear, and a lynx's eye, together with a quick perception, endowed with quick impulses for acting, so necessary to each? That he should be "fond of his profession," and "indefatigable in the pursuit of it;" "sober and exact," "sensible," and "good tempered?" It is not necessary that either a huntsman or a soldier should be a man of letters; some of the best among the former have been scarcely able to read; and there have been but few Cæsars who could fight and write; but a good understanding is put to the test by both the one and the other; and although we do not mean to place the servile situation of a huntsman on a level with the honourable profession of the soldier, each requires, in a high degree, a good, sound understanding, and a manly exertion of talent.

But the office of huntsman to fox-hounds is not always intrusted to servile hands. It has long been the ambition of masters of packs to hunt their own hounds; and although the fashion has become more prevalent within the last thirty years than it was in the earlier days of fox-hunting, yet we could bring forward some instances of what are called gentlemen-huntsmen of pretty long standing. His Grace the Duke of Cleveland, and Sir Richard Puleston, Bart. each hunted his own hounds for nearly forty years; and the late William Leche, Esq. of Carden-Hall, Cheshire, was his own huntsman for an equally long period. Coming next to them in chronological order, stand Messrs Ralf Lambton, Musters, Thomas Assheton Smith, Lord Segrave, Sir Bellingham Graham, Bart., Mr Osbaldeston, Mr Nicoll, the Earl of Kintore, Mr Smith, late of the Craven, the Honourable Grantley Berkeley, and several more of a more recent date. There can be no doubt that no man enjoys hunting to perfection equally with him who hunts his own hounds; nor can there be any reason assigned why an educated gentleman should not excel, in any ardent and highly scientific pursuit, an uneducated servant; nevertheless, we do not think that, throughout the fox-hunting world in general, gentlemen-huntsmen have been so popular as might have been expected; and in some countries that are hunted by subscription, an exception is taken against the master of the pack being the huntsman. That it is a very laborious office when efficiently executed, both in the kennel and the field, is well known to those who have filled it; but, *labor ipse voluptas*, we have seen a pains-taking zeal displayed in the master which we have too often seen wanting in the servant; and we could name a nobleman who used frequently to tell his huntsman, when drawing for his second fox, that he was "thinking more of his dinner than of hunting."

In the earliest days of English hunting, gentlemen huntsmen were in high estimation; and a reference to *Domesday-book* will show that Waleran, huntsman to William the Conqueror, possessed no less than fifteen manors in Wiltshire, eight in Dorsetshire, together with several in Hampshire; and his name occurs on the list of tenants *in capite* in other counties. The same venerable record of antiquity describes the extensive possessions of other huntsmen, bearing the names of Croc, Godwin, Willielmus, gentlemen of consideration in those times, in which, according to Froissart, the ardour of the chase was carried to a pitch since unequalled by the Norman lords, some of them having kept sixteen hundred dogs, and a proportion-able number of horses, for the chase.[1] But we may go still farther back, to a very barbarous age, for the respect in which huntsmen have been held by kings and legislators. The temperate but brave Agesilaus, and even the luxury-destroying Lycurgus, provided for the bountiful entertainment of their huntsmen on their return from the chase; a pursuit which they believed to be so agreeable to the gods, that they offered the first fruits of their sports to Diana.

The Duties of a Huntsman.

The situation of huntsman to a pack of fox-hounds is one of great responsibility, and, if the breeding as well as hunting of them be left to him, a very arduous undertaking. Nor does it end here. There is great call for judgment in feeding hounds to answer every purpose, such as long draws, severe days, and at the same time to go the pace without showing distress, and to come home at night with their sterns up, and looking fresh. Here variety of constitution increases the difficulty; for, to please the eye, hounds should look level in their condition, as well as even in point of size. One hound will not bear to have his belly more than half filled; another will not fill his when he may; and still each must be made equal in strength and wind to the other, to stand hard work and go the pace without distress. A huntsman must have a very watchful eye over their condition, which will be effected by work and weather; and he must be pathologist enough to foresee and provide against the alterations which such circumstances produce. He has need also to be a physiologist, to enable him to exercise a sound judgment in breeding his hounds after a certain form and fashion, which are absolutely essential to their doing well, and at the same time pleasing the eye. Then look at him in the field, with a hundred eyes upon him, and a hundred tongues to canvass all his acts. Here he should be a philosopher.

In the Field.

A huntsman is expected to bring his hounds to the cover side in a high state of condition, at all seasons of the year. They should be seen quietly grouped about his horse's heels, when he is waiting for the hour of throwing off, without a whip stirring, or even an angry word said to them. This is a time when they are often subject to the inspection of strangers, and a first impression goes a great way. When the master gives the word to draw, they should approach the cover at a gentle trot, one whipper-in riding in their front; and when within about a stone's throw, they may dash into it with as much spirit as they like. Not a word need be said by way of caution, unless it appears to be especially called for, when "gently, there," by the first whipper-in, and one smack of his whip, will generally have the desired effect. But we like to see the huntsman alive at this moment, as well as his hounds. Homer compares hounds cheered by their huntsman, to troops encouraged by a skilful general; and doubtless there is a similarity in the effect. Putting hounds out of the question, there is something very cheering to the field in the "cheering holloa" of a huntsman, when encouraging his hounds to draw; and it also answers two good purposes. Should a hound get wide of the pack, or hang behind in the cover, or should any of the field be at a loss, which often happens in woodlands, the "pipe" of the huntsman is an unerring guide to all. How necessary is it, then, at all events how desirable, that, like Ajax, he should be βοὴν ἀγαθὸς, "renowned for the strength of his voice," and, we may add, for the melodiousness of it. He should likewise blow a horn well; and if he varies the blast, to make himself more intelligible to his hounds, he will find his advantage in it. We wonder this is not more practised than it is. Independently of the common *recheat*, why not have the "view horn" as well as the "view holloa?" But too much horn, like *vox et prœterea nihil,* is bad, making hounds apt to disregard it; yet a huntsman would be sadly at a loss without it, not only in getting hounds away from cover and in chase, but in drawing large covers, in which they will occasionally get wide. Here a twang of the horn saves a huntsman's voice in bringing them over to him. One short blast is sufficient.

> .... "He gave his bugle-horn a blast,
> That through the woodlands echoed far and wide."

The following observations on holloaing are from the pen of an old sportsman. They contain hints that it would often be advisable to profit by; and they apply not only to huntsmen, but to the field. "A general rule as to *hallooing* is, never to halloo unless you can give a good reason for so doing. A constant and indiscriminate use of the voice is blameable in a huntsman; his hounds, by constantly hearing his voice, will soon learn to pay no more attention to it than they do to the singing of the lark, and they will not come to him when they are called. Some huntsmen, in making a cast, try that part of the ground where they can most conveniently ride, instead of that where it is most likely the fox is gone. Others ride on hallooing, without regarding their hounds, while making their cast; their own noise then prevents them from hearing their hounds, who often take the scent without their being aware of it."

"No person should halloo that is not well forward. It signifies little what words you use, as a hound's knowledge of language is confined to a view halloo, a call, and a rate: it is the tone of the voice, and not the words, that they understand; and hounds will always draw to the voice, if it be not a rate. This shows the impropriety of hallooing behind hounds. In running with good scent, if you are up with the pack, a cheering halloo does no harm; the hounds will not attend to it, and it is expressive of the pleasure of the hallooer. Never cap hounds with loud halloos to a bad scent; capping makes them wild and eager, and should never be done but when the scent is high. Hounds should be brought up gently to a cold scent." Holloaing to hounds is often necessary, and highly useful when done with judgment; but the word "tallyho" loses many a good run; as, unless a fox is gone clear away from his cover, it occasions him to turn back often into the mouth of the hounds.

Dog Language.

It is true, no correspondence can subsist between beings whose natures are separated by a chasm so wide as that between rational and irrational animals; and it is with a view of adapting our meaning to the level of their understandings, that we generally address or converse with brutes in a silly unmeaning manner; which gave rise to the remark, that children, or men who act like children, have animals more immediately under their control than the philosopher who is replete with wisdom. But we may look farther into the subject than this. If the Almighty had not manifested some portion of his attributes by means which are on a level with the capacity of the human race, man must have remained for ever ignorant of his Maker. The power of language, however, between man and man, is prodigiously increased by the tone in which it is conveyed. The vagrant when he begs, the soldier when he gives the word of command, the senator when he delivers an oration, and the lover when he whispers a gentle tale to his mistress, all differ in the key in which they speak; and it is thus that huntsmen and whippers-in make themselves intelligible to hounds. They do not speak to them in an unmeaning manner, or after the manner of children; but in short and pithy sentences, every word of which is law. The method of doing this, however, admits of several degrees of excellence; but the huntsman who is endowed by nature with a clear, sonorous voice, in a well-pitched key, and knows when to use it with effect, contributes greatly to the enthusiasm of fox-hunting, and no doubt to the success of it.

---

[1] See Froissart, tom. iv. c. 27.

Without entering again into the wide range of hunting, we cannot do more than add a few maxims which may be observed by a huntsman in the field. In drawing for your fox, don't be persuaded always to draw up wind. In the first place, you are in danger of chopping him; secondly, he is sure then to go down wind at starting; and, thirdly, you may drive him into a worse country, or from his point. When found, get after him as quickly as possible if you have a body of hounds with you; if not, you will have a better chance of sport if you can wait till the body come up. This is easily done by a twang of the horn, or a false holloa, if hounds are under good command, and the convenient opportunity be seized upon. Keep near to them in chase, with your eye on *the body* of the pack, as well as on such hounds as may be leading; the body are more certain to be right. Next to knowing where a fox is gone, is knowing where he is not gone; therefore, in your cast, always make good the head. This you will do for your satisfaction; but hounds are seldom at fault for the scent a-head, when the chase has been at all warm, that is, on a fair scenting day; for if the fox be gone forward, wherefore the fault? Good hounds will seldom or never leave a scent a-head, unless the ground be stained by sheep or cattle, or when the chase leads over dry ploughed land, hard and dry roads, &c. It is high odds that your fox has turned to the right or to the left; but although his point may be back, he cannot well run his foil, from the number of horsemen that are generally in the rear of fox-hounds. Recollect your first check is generally the most fatal to sport, and for these reasons: Your hounds are fresh, and perchance a little eager; they may have overrun the scent for some distance, owing to their being pressed by the horses, which are also at this time fresh; nor will they always get their heads down as soon as they should do, from the same exciting causes. Again, your check now generally arises from a short turn, the fox having been previously driven from his point, which he now resolves to make; and he will make it at all hazard at certain times. When your hounds first "throw up" (*i. e.* check), leave them alone if they can hunt; but, disregarding what the "old ones" say on this subject, as inapplicable to these fast times, don't be long before you take hold of them, and assist them, if they cannot. We would not go from scent to view; yet hounds in these days that will not bear lifting are not worth having. But do all this quietly as well as quickly. Turn your horse's head towards the line you think your fox is gone; and the first moment you see all their heads up, that is, if they do not hit him off, put your horn to your mouth for one blast or two, and trot away to still more likely points. If your pack will divide when casting, so much the better; but if they are good for any thing, they will be making their own cast whilst you are making yours, by not keeping at your horse's heels, but spreading as they go.

When you have hit upon his point, if a single hound goes off with a good scent, get the body to him as quickly as you can; but not so if the scent be not warm. In the latter case, your hounds will be in expectation of a fresh fox, and will be in a hurry; the hound that is forward will be lifted, and in all probability you will have to seek for the scent again. Go gently, and your hounds, if steady, will settle to it. Likewise, if, when at check, you are holloaed to a spot where a fox has been viewed, *stand still*, and say nothing at the moment the first two or three hounds throw their tongues. If you hurry the body on immediately, the scent will often be lost if the fox has been a few minutes gone. If it can be done, give your hounds the wind at a crisis like this. Again, when a fox has been viewed, and you go directly to holloa, do not take your hounds to the extreme distant point at which he was viewed, but a hundred yards behind it; and for this reason. If you take them to the extreme point, and they do not take up the scent at once, you have then to make your cast at a venture; whereas, if you lay them on at that distance behind it, you have somewhat of a guide to that extent, as to the line towards which you should draw them.

The following further hints may be serviceable, or at all events they relate to hounds at check. In trying back, hounds have this advantage. It is evident the fox has come the line, up to the point where the check occurred; and he must be gone either to the right or the left of it, or back. We make this observation, because so much has been said about the straight running of foxes, which is far from true; and the necessity of persevering in the cast a-head with the fox, and back, on the foil, with the hare. The more hounds spread, within reason, in this backward cast, the better will be the chance of making the check a short one. Again, if at check on a road, or foot-path (the latter not often run over by foxes), when you observe some of your best hounds failing to make it good, on one side of either, it is reasonable to suppose the fox is gone on the other. If your hounds check in a cover in the middle of a run, and the fox is viewed away from it, try and get your hounds together as much as you can in the short time that can be allowed for it, *before you cap them to the scent.* It generally ensures a good finish, from two obvious causes. First, hounds get fresh wind; and, secondly, they will have a better chance to carry a good head, which generally ends in blood, and in blood well earned; for the fox is more likely to stand longer, and go straighter, for not having been viewed by hounds when he broke. But the most difficult point for a huntsman to decide upon promptly is, when his pack divides, which division is on the hunted fox. If it happen in cover, his ear is his surest guide, as the cry is louder and stronger on a fresh-found fox, than on one which has been for some time on foot. If when out of cover your pack should split on two separate scents, you should get as near as you can to what you imagine to be the chase, giving view holloas every yard you go; also sending one of your whippers-in to stop the other hounds. Your choice will doubtless be directed by several circumstances. You will first look for your truest and best line-hunting hounds, and next, to the points your first fox would be likely to make for; and if your choice fall upon the lot that are going farthest up the wind, the other will be more likely to hear them running; and, should they come to a check, to join cry again perhaps before a whipper-in can get to stop them.

To the above we add a few general rules. Don't be dispirited at a succession of bad sport, for it is not within your control, good hounds and sport not being naturally co-existing circumstances. Be as zealous as you please in the field, but temper your zeal with judgment, and don't weary your hounds by long draws, on days which bid defiance to sport. It was once justly observed, that those who seek pleasure from the chase must ask permission of heaven; and the case still remains the same. Hounds without a scent resemble a man running in the dark; neither can make head against such fearful obstructions; and on stormy days, with a very high wind, if you have influence with your master, persuade him to let you go home after the first failure. It is not generally known what mischief even one such day does to some hounds. Don't set too high a value on blood, unless well earned; it is the result of want of reflection alone that has set any value whatever upon it, when otherwise obtained. Mob a bad fox in a cover if you like; but never dig out a good one, unless your hounds have almost viewed him into a spout, and you can bolt him before the excitement subsides. Never break ground in a country belonging to another pack of hounds, nor dig for a fox in a moin earth in your own. Many a bitch fox, heavy with young, has been killed by this means in the spring, instead of the one that was hunted and marked to ground; and be assured that sportsmen in general do not estimate the goodness of a pack of hounds by the noses nailed against the kennel door. Lastly, keep your field back from pressing on your hounds in chase, and still more so when in difficulties, as well as you can; but don't suffer your zeal to carry you too far on this point. Remember the apostolic precept, "BE COURTEOUS."

The modern annals of sporting contain the names and characters of several very eminent huntsmen, whose conduct and abilities would have done credit to any other situation of life to which it might have been their lot to have been called. Considering the responsibility of their office, the severity of their work, and the risks they run, they are not supposed to be too highly paid in wages, say on the average L.100 per annum, besides their board; but, from perquisites, such as annual presents from gentlemen who attend the hounds which they hunt, and drafted hounds sold to other packs, they may realize the like sum in addition.

The office of whipper-in is, in our opinion, thought more lightly of by the sporting world in general than it deserves to be; and, as we shall show, we have the great Beckford on our side. We never saw a steady pack of hounds without at least one good whipper-in, and we are quite sure we never shall; but we have seen many of these red-coated youths who might have been better employed at the plough-tail—who, like Cicero's lawyer, belonged rather to the profession than the science. "If he has genius," says Beckford, "he may show it in various ways; he may clap forward to any great earth that may by chance be open; he may sink the wind to holloo, or mob a fox when the scent fails; he may keep him off his foil; he may stop the tail hounds, and get them forward; and has it frequently in his power to assist the hounds without doing them any hurt, provided he has sense to distinguish where he is wanted most. Besides, the most essential part of fox-hunting, *the making and keeping the pack steady*, depends entirely upon him, as a huntsman should seldom rate, and never flog a hound. In short, I consider the first whipper-in as a second huntsman; and, to be perfect, he should be as capable of hunting the hounds as the huntsman himself. He should not be conceited, but contented to act an under part, except when circumstances may require that he should act otherwise; and the moment they cease, he must not fail to resume his former station."

To the above excellent remarks we have very little to add. We only recommend, when a huntsman is casting his hounds, that a whipper-in should turn them to him always as gently as he can, and with little noise; by which means they will *draw* towards him, trying for the scent as they go; whereas loud and repeated rates and cracks of the whip make hounds fly to their huntsman at this time with their heads up. When they are drawing properly towards him, not a word should be said; a whipper-in riding outside of them will be sufficient.

It is scarcely necessary to say, a whipper-in, to be perfect, should be an accomplished horseman, as nothing requires a much firmer and nicer hand than the act of following a hound over open ground to flog him. A whipper-in, however, should always hit a hound first, and rate him afterwards, and be able to hit hard when occasion requires it. A riotous fox-hound cannot be trifled with, if he is to be cured of his evil ways; and let the lash fall heavily when necessary, but at no other time. Above all, let the whipper-in have an eye to a skirter: skirting is the least pardonable fault a hound can possess, because he is then deviating from his nature, and has not the force of impulse to plead, which the hound that runs riot has. (B. B. B. B.)

HUNTINGDON, a market-town, the capital of the county of that name, sixty-four miles from London by Buckden, and fifty-nine by Royston. It stands on a level plain on the river Ouse, which is navigable for barges to Bedford, and by which a supply of coals and other heavy articles is conveyed. It contains two parish churches, and a good county-hall, where the assizes are held; and it has a good market, especially for corn, on Saturday. It is governed by a mayor, twelve aldermen, and a common council, and returns two members to parliament by about 380 voters. The inhabitants amounted in 1801 to 2035, in 1811 to 2397, in 1821 to 2806, and in 1831 to 3267.

HUNTINGDONSHIRE, an inland county of England, and, except Rutlandshire, the smallest of the whole. It is bounded on the north-east and east by Cambridgeshire, on the north-west and west by Northamptonshire, and on the south by Bedfordshire. Its greatest breadth is twenty-three miles, and its greatest length thirty miles, and its square contents are 350 miles.

The county has four hundreds, with six market-towns, and 104 parishes, the total population of which amounted in 1801 to 37,568, in 1811 to 42,208, in 1821 to 48,771, and in 1831 to 53,100. The occupiers of land employing labourers were 857, of land employing no labourers 397, of labourers employed in agriculture 5967, of persons employed in manufactures 290, of those employed in retail trade and handicraft 3488, of capitalists, bankers, &c. 401, of labourers not agricultural 971, of male servants 454, other males twenty years of age 649, and female servants 1941.

The principal towns, and their population, are,—

Huntingdon	3267
St Ives	3314
Ramsey	3006
St Neots	2617
Godmanchester	2146
Kimbolton	1584

The county returns two members to the House of Commons, the voters are about 3200, and the places for poling are Huntingdon and Stilton. The borough of Huntingdon also returns two members.

The appearance of the county is of three descriptions. In the south-east it is an extensive plain of rich meadow land, the middle varying in its surface with gentle undulations, and without many enclosures or many woods; the higher part was anciently a forest, and still contains a great extent of woodland, the foliage of which gives beauty to the scenery. On the north-eastern side a portion of the county is fine land, comprising a part of what is commonly called Bedford level, comprehending nearly one fifth of the whole county.

The two most considerable rivers are the Ouse and the Nen. The Ouse enters from Bedfordshire, and crossing the whole of the county, passes into Cambridgeshire in its way to the German Ocean. It is navigable in its whole extent through Huntingdonshire, and forms an important means of intercourse. The Nen enters from Northamp-

Huntingdonshire.

tonshire, and runs to the marshes; it is also navigable along the greater part of its course. Besides these, the Cam passes through a part of the county. There are three lakes, viz. Whittlesea-mere, Ramsey-mere, and Ugg-mere; the first of these is the largest, and covers an area of several miles in extent. It affords excellent fishing, and pleasant sailing, which induces many parties of pleasure to visit it in the summer season. Projects for draining this lake have been formed, as the water is not deep, and the soil excellent; but they have not yet been carried into execution.

The county of Huntingdon scarcely contains any manufactures, excepting some spinning, performed by the females; but the improvements of machinery in other districts have much diminished that mode of employment. The only trade is that of corn, cattle, and the wool of the few flocks of sheep.

Agriculture is the principal pursuit of the district. The marshes and meadows are highly productive, and many oxen are fattened on them, without any other food than their natural grass. Much of this land is under the plough, and produces most abundant crops of oats and cole-seed; the mills for making the latter into oil are numerous. The hay produced from these fens is very considerable, but on the banks of the rivers they are subject to great floods, which sometimes destroy the harvest of the year. Though these lands are very valuable, yet the expense of draining them causes a great deduction from their value.

The soils in the upland parts of the county are various, but consist principally of a tenacious clayey loam, or of a deep gravelly loam with some clay. Much of this is in open common fields, where each occupier is compelled to follow a rotation like that of his neighbours. On the best of these lands the usual course of cropping is a year's fallow, then wheat or barley, next beans, and then barley or wheat. On the land of a quality somewhat inferior, a three-course rotation of fallow, wheat, and peas or beans, is pursued. In those fields which are calculated for turnips, that root is succeeded by barley and wheat, or by wheat and barley. The average produce of the lands is stated at five quarters of barley, four of oats, and three and a half of wheat, to the acre. The excellent practice of sowing clover between two corn crops is followed to a very small extent. The farms are generally small; few rentals exceed L.200 per annum.

The sheep of Huntingdonshire are a mixed race, composed of crosses of the Lincolnshire and Leicestershire breeds with the native kinds. They are without horns, and of very imperfect shape, but are found profitable from the quantity of wool they produce, their fleeces usually weighing from seven to eight pounds each. The sheep of the original race of the county are much inferior to those produced by the crossing with the better kinds; many of these are still found in the open commons, and their fleeces seldom exceed four pounds in weight. The cows are bred with little attention, and are a compound of many races. Very little butter or cheese is made, the principal object being the suckling of calves to supply veal for the London markets. Many horses are bred in the lower part of the county, but without much attention to their races. From this practice of breeding, it has become very general to execute all the agricultural work with mares.

The remains of antiquity in this county are principally of Roman origin; amongst them are the vestiges of the three roads which were constructed by that people across the country. The remains of Ramsey Abbey and Castle, the seat of the family from which Oliver Cromwell, a native of this county, sprung, are of venerable date. The monks who formerly occupied it were highly celebrated for their knowledge of the Hebrew language. The churches of Bluntisham, St Ives, and St Neots, and the Castle of Kimbolton, exhibit marks of high antiquity.

Huntsp Hurd.

The most remarkable noblemen and gentlemen's seats are, Kimbolton, Duke of Manchester; Bucden Palace, Bishop of Lincoln; Connington Castle, J. Heathcote, Esq.; Elton, Earl of Carysfort; Hinchinbroke, Earl of Sandwich; Overton Longueville, Earl of Aboyne; Gains Hall, Sir James Duberly; Paxton Place, P. Stanley, Esq.; Ramsey, William Henry Fellowes, Esq.; Stirtloe, Launcelot Brown, Esq.; Stoughton, Earl Ludlow; and Upwood, Sir Richard Bickerton. (See Brayley's *Beauties of England and Wales*, Stone's *General View of Huntingdonshire*, and *Population Returns.*)

HUNTSPILL, a town of the county of Somerset, in the hundred of North Petherton, 155 miles from London. It stands on an estuary at the mouth of the river Parret, which there falls into the Bristol Channel. The inhabitants amounted in 1801 to 1012, in 1811 to 1119, in 1821 to 1337, and in 1831 to 1503.

HURD, Richard, an eminent and learned English prelate, was born at Congreve, in the parish of Penkrich, Staffordshire, on the 13th of January 1720. He was the second son of John and Hannah Hurd, whom he describes as "plain, honest, and good people, farmers, but of a turn of mind that might have honoured any rank and any condition;" and they appear to have been solicitous to give their son the best and most liberal education. Young Hurd received his elementary education at the grammar-school of Brerewood, and, in 1733, was admitted of Emmanuel College, Cambridge, though he did not go to reside there until a year or two afterwards. He took the degree of bachelor of arts in 1739, and that of master in 1742; the same year he was elected a fellow, and ordained deacon in St Paul's Cathedral, London; and in 1744 he was admitted into priest's orders at Cambridge. Dr Hurd's first literary production was Remarks on Weston's *Inquiry into the Rejection of the Christian Miracles by the Heathens*, published in 1746; and, in 1748, upon the conclusion of the peace of Aix-la-Chapelle, he contributed some verses to the university collection for 1749. In the same year he took the degree of bachelor of divinity, and published his Commentary on the *Ars Poetica* of Horace, in which he laboured to prove that the Roman poet has treated his subject with systematic order and the strictest method; an idea which has been strenuously combated by several eminent critics. In the preface to this Commentary he took occasion to compliment Warburton in a manner which won him the favour of that learned dogmatist, and procured for him a return in kind in the bishop's edition of Pope's works, where Hurd's Commentary is spoken of in terms of the highest approbation. This commerce of flattery gave rise to an intimacy between these persons, which continued unbroken during their lives, and is supposed to have exercised considerable influence on the opinions of Hurd, who was long considered as the first scholar in what has been termed the Warburtonian school. This Commentary was reprinted in 1757, with the addition of two Dissertations, one on the drama, the other on poetical imitation, and a letter to Mr Mason on the Marks of Imitation; in 1765, a fourth edition, corrected and enlarged, was published in three vols. 8vo, with a third Dissertation on the idea of universal poetry; and the whole was again reprinted in 1776. This work fully established the reputation of Hurd as an elegant and acute, if not always a sound and judicious critic. In May 1750, he was appointed by Sherlock, bishop of London, one of the Whitehall preachers. About this period the university of Cambridge was disturbed by internal divisions, occasioned by an exercise of discipline against some of its members who had been wanting in respect towards those invested with authority. The delinquents having refused to submit to the punishment awarded, and appealed from the vice-chancellor's jurisdiction to that of the senate, the right of the university, and those to whom its power was delegated, became thus a subject of discussion, and several pamphlets appeared on both sides of the question. Amongst those who signalized themselves on this occasion may be mentioned Hurd, who wrote The Opinion of an eminent Lawyer (the Earl of Hardwicke) concerning the Right of Appeal from the Vice-Chancellor of Cambridge to the Senate, supported by a short historical account of the Jurisdiction of the University; in answer to a pamphlet, entitled *An Inquiry into the Right of Appeal from the Vice Chancellor*, 1751, in 8vo; a production which passed through three editions, and was defended in a Letter to the Author of a Further Inquiry, 1752, in 8vo, by whom it had been attacked. In 1751, he published a Commentary on the Epistle to Augustus; in 1753, a new edition of both commentaries, with a dedication to Warburton; and the same year two occasional sermons, one preached at the Norwich assizes, and the other in behalf of the charity schools at Cambridge, but neither of which has been retained in his works. The friendship he had formed with Warburton continued to increase by mutual good offices; and, in 1755, Hurd eagerly embraced an opportunity which offered of evincing the warmth of his attachment. Dr Jortin having, in his Dissertations, spoken of Warburton with less deference and submission than the exactions of an overbearing and insolent superiority could easily tolerate, Hurd wrote a bitter satire, entitled the Delicacy of Friendship, a seventh Dissertation, addressed to the author of the sixth, 1755, in 8vo; a production in which he was betrayed into too close an imitation of Warburton's manner, and displayed a degree of warmth far beyond any thing that the supposed offence could either call for or justify. Hurd accordingly took pains to suppress the pamphlet; but, in 1788, it was republished in a volume entitled Tracts by Warburton and a Warburtonian. Hurd continued to reside at Cambridge, in learned retirement, if not learned ease, until 1756, when, on the death of Dr Arnold, he succeeded, as senior fellow of Emmanuel College, to the rectory of Thurcaston, to which he was instituted in 1757, and where, having entered into residence, he continued to prosecute his studies, which were principally confined to subjects of elegant literature. The Remarks on Hume's Essay on the Natural History of Religion appeared soon afterwards. But Warburton appears to have had the chief hand in the composition of that tract, which, accordingly, we find republished by Hurd in the quarto edition of that prelate's works, and enumerated in the list of them. It appears to have occasioned some uneasiness to Hume, who, in the account of his own life, notices it with a degree of acrimony quite unusual in his compositions. In 1759, Hurd published a volume of Dialogues on Sincerity, Retirement, the Golden Age of Elizabeth, and the Constitution of the English Government; and this was followed by his Letters on Chivalry and Romance, which, with his Dialogues on Foreign Travel, were republished in the year 1765, with the author's name, and a preface on dialogue writing. In the preceding year, he published another of those zealous tracts in vindication of Warburton, which have added little to his fame as a writer, and procured him the reputation of an illiberal and discourteous polemic. It was entitled a "Letter to the Reverend Dr Thomas Leland, in which his late *Dissertation on the Principles of Human Eloquence* is criticised, and the Bishop of Gloucester's idea of the nature and character of an inspired language, as delivered in his Lordship's *Doctrine of Grace*, is vindicated from all the objections of the learned author of the Dissertation." This, with Hurd's other controversial tracts, has been republished in the eighth volume of the authorized edition of his works, where we find prefixed to it, by way of advertisement, the following lines, written by the author not long before his death: "The controversial tracts which make up this volume were written and published by the author at different times, as opportunity invited, or occasion required. Some sharpness of style may be objected to them, in regard to which he apologises for himself in the words of the poet:

> .... Me quoque pectoris
> Tentavit in dulci juventa
> Fervor ....
> .... nunc ego mitibus
> Mutare quæro tristia."

In 1762, the sinecure rectory of Folkton was conferred on him by Lord Chancellor Northington; in 1765, he was chosen preacher of Lincoln's Inn; and in August 1767, he was collated to the archdeaconry of Gloucester by Bishop Warburton. In July 1768, he was admitted doctor of divinity at Cambridge; the same day he was appointed to open the lecture founded by Warburton for the illustration of the prophecies; and the Twelve Discourses which he preached there were published in 1772, under the title of an Introduction to the Study of the Prophecies concerning the Christian church, and in particular concerning the church of Papal Rome. This volume drew from Gibbon, under a fictitious name, a private letter to the author respecting the book of Daniel, which Dr Hurd answered; but it was not until the appearance of the historian's Miscellaneous Works, in which Dr Hurd's answer was printed, that the latter knew the name of his correspondent. In 1769, he published the Select Works of Abraham Cowley, with a preface and notes, in two vols. 8vo; an edition which has been condemned as interfering with the totality of Cowley's works, and which certainly is not the most judicious of Dr Hurd's undertakings. In 1775, he was, by the recommendation of Lord Mansfield, promoted to the bishopric of Lichfield and Coventry, consecrated early in that year, and, soon after entering on the episcopal office, he delivered a charge to the clergy of the diocese, as well as a Fast Sermon for "the American rebellion," which was preached before the House of Lords. In May 1781, Bishop Hurd received a gracious message from his majesty, conveying to him an offer of the see of Worcester, with the clerkship of the closet, both of which he accepted. Nor did his majesty's kindness stop here. For, on the death of Dr Cornwallis, in the year 1783, he was offered the archiepiscopal see of Canterbury, with many gracious expressions, and even pressed to accept it; but he humbly begged leave to decline it, "as a charge not suited to his temper and talents, and much too heavy for him to sustain in these times," alluding, we presume, to the distractions arising from the conflict of political parties. In 1788, Hurd published a complete edition of the works of Warburton, in seven vols. 4to; but the Life did not appear until 1795, when it came forth under the title of a Discourse by way of General Preface to the quarto edition of Bishop Warburton's works, containing some account of the Life, Writings, and Character of the Author. This work excited considerable attention, and the style is equally remarkable for its purity and elegance; but the stream of panegyric is too uniform not to subject the author to the suspicion of long-confirmed prejudices. Even the admirers of Warburton would have been content with less laborious efforts to magnify him at the expense of all his contemporaries; and, conscious that imperfection is the common lot of all men, they conceived that age and reflection should have abated, if not wholly extinguished, the unworthy animosities of times gone by. But in all this they were disappointed. Hurd was a true disciple of the great dogmatist; and hence it was with regret they observed the worst characteristics of Warburton, his inveterate dislikes, his fierce contempt, and his sneering rancour, still employed to perpetuate his personal antipathies, and employed too against such men as Secker and Lowth. If these were the feelings of the friends who venerated Warburton and esteemed Hurd, others, who never had much attachment to the Bishop of Gloucester or his school, found little difficulty in accumulating against his biographer charges of gross partiality and illiberal abuse. The remainder of Hurd's life appears to have been spent in the discharge of his episcopal duties, and in studious retirement. He died on the 28th of May 1808, being then in his eighty-ninth year. As a writer, his taste, learning, and talents have been universally acknowledged; and though, like his master, contemptuous and intolerant, he was nevertheless shrewd, ingenious, and original. In his private character he is said to have been in all respects amiable; nor were the relations of life in any degree embittered by the gall and wormwood which so frequently flowed from his pen. (A.)

HURDA, a town and small fort of Hindustan, in the Mahratta territories, in the province of Khandesh, situated in a country generally open and well cultivated. Long. 77. 18. E. Lat. 22. 24. N.

HURDLE is the name of a sledge used to draw traitors to the place of execution. The Romans had a kind of military execution for mutineers, called *putting to death under the hurdle.* The manner of it was this: The criminal was laid at his length in shallow water, under an hurdle, upon which were heaped stones, and so pressed down until he was drowned.

HURDLES, in *Fortification*, are made of twigs of willows or osiers interwoven together, and sustained by long stakes. They are made in the figure of an oblong square, the length being five or six feet, and the breadth three and a half. The closer they are wattled together the better. They serve either to render the batteries firm, or to consolidate the passage over muddy ditches, or to cover traverses and lodgments for the defence of the workmen against fireworks or stones thrown against them.

Hurdles, in *Husbandry*, certain frames made either of split timber, or of hazel-rods wattled together, to serve as gates in enclosures, or to make sheep-folds, &c.

HURDWAR, or Haredwara, a town of Hindustan, province of Delhi, a great mart of commerce, and a celebrated place of Hindu pilgrimage, situated on the west side of the Ganges, where it issues from the northern hills. The town is not large, having only one street about fifteen feet in breadth, and one furlong and a half in length. Pilgrims of both sexes resort annually thither from all parts of India to perform their ablutions in the sacred Ganges. The month of April is the time appointed for this concourse of pilgrims; and great numbers of merchants also attending, one of the largest fairs known in Hindustan is held here. It is calculated that in general about 300,000 persons are collected on this occasion; but once in twelve years, when particular ceremonies are observed, the number is increased to a million. In April 1809, it was computed that two millions of strangers were assembled. The chief articles brought thither for sale are horses, mules, camels, tobacco, antimony, assafœtida; dried fruits from Cabul, Candahar, Moultan, and the Punjab; shawls, cloaks, &c. from Cashmere and Amritsir; spotted turbans, looking glasses, toys, with various manufactures in brass and ivory, from Jeypoor; shields from Rohilcund, Lucknow, and Silhet; bows and arrows from Moultan and the Doab; rock-salt from Lahore; baftas and piece-goods from Rahn, a large city in the Punjab; many camels, and a species of flannel, from the Marwar country; and from the Company's provinces Kharwa muslins, sarsnet, cocoa nuts, and woollen cloths of a coarse quality. The merchants who frequent this fair travel in large caravans, and are frequently infested on the roads by freebooters, who watch their opportunity and cut off stragglers. During the Mahratta dominion, a poll tax and heavy duties were imposed on all the cattle. But these have all been repealed by the British, and every encouragement is now held out to merchants. In such a vast concourse of people from all quarters, disputes were formerly very frequent. But, owing to the strict police maintained by the British, these fairs have lately ended without bloodshed, to the surprise and satisfaction of the vast multitude, who were accustomed to see bloody quarrels at the Hurdwar fair. The stream divides itself into three channels at Hurdwar, the principal of which is on the western side, running along a bank named Chandnee Ghaut. At the foot of the pass into the mountains is a Goorkah fort, belonging to Nepaul, to which many hundreds of slaves are annually brought down from the hills and exposed to sale. The travelling distance from Calcutta by Moorshedabad is 1080 miles, by Birbhoom 975 miles, from Delhi 117 miles, and from Lucknow 311 miles. Long. 78. 2. E. Lat. 29. 57. N.

HURLY-Burly, in vulgar language, denotes confusion or tumult, and is said to owe its origin to two neighbouring families, Hurleigh and Burleigh, which filled their part of the kingdom with contest and violence.

HURON, a vast lake of North America, situated between the 80th and 84th degrees of west longitude, and between the 43d and 46th degrees of north latitude; from which the country contiguous to it is called the country of the Hurons, a people whose language is spoken over a great extent of America.

HURREEPORE, in Hindustan, the capital of a district of the same name belonging to the Sikhs, which is situated between the 32d and 33d degrees of north latitude, and is intersected by the Beyah river. The town is situated in the province of Lahore, 100 miles east-north-east from the city of Lahore. Long. 75. 31. E. Lat. 24. 19. N.

HURRIAL, a town of Bengal, district of Rajesky, where the East India Company have a commercial residency for the purchase of cloths. The adjoining country is under water during the rainy season, and the town can only at that time be approached in boats. Long. 89. 17. E. Lat. 24. 19. N.

HURRICANE, a general name for any violent storm of wind, but commonly applied to those storms which happen in the warmer climates, and greatly exceed the most violent storms known in Europe.

HURST, Hyrst, or Herst, are derived from the Saxon *hyrst*, meaning *a wood*, or *grove of trees*. There are many places in Kent, Sussex, and Hampshire, which begin and end with this syllable; and the reason may be, because the great wood called *Andreswald* extended through these counties.

HUSBANDRY, as defined by some, includes not only agriculture, but several other branches connected with it, such as the rearing of cattle, the management of the dairy, making butter and cheese, raising flax, timber, and so forth. See Agriculture.

HUSKISSON, Right Honourable William, a distinguished statesman, was born at Birch Moreton, in Worcestershire, on the 11th of March 1770. After receiving a liberal education, he was sent to Paris for instruction in physic, the profession to which he was originally destined. Whilst in the French capital, however, circumstances occurred which induced him entirely to alter his course of life. On the breaking out of the French revolution, he espoused the popular side, and became an active member of the London Corresponding Society, but not, as has been sometimes asserted, of the Jacobin Club of Paris. Through the influence of a friend he was introduced to Lord Gower, then British ambassador at Paris, and was afterwards appointed his private secretary. On his return to England, the talents of Mr Huskisson attracted the attention of Mr Pitt and Mr Dundas, and in 1795 he was appointed chief clerk in the office of the latter, at that time secretary of state for the war department. In the following year he succeeded to the office of under secretary; and being found a valuable man of business, he was brought into parliament for the borough of Morpeth. In his subordinate connection with the ministry, Mr Huskisson shared the varying fortunes of those in power, retiring from office and returning to it with his superiors. During the early part of his parliamentary career he did not speak much, but he was exceedingly useful to the ministry in matters of business, particularly of a financial nature. On the return of Mr Pitt to power in 1804, he was appointed one of the joint secretaries to the treasury. During Mr Fox's short administration he was in opposition, but he returned with Mr Percival, and resumed his secretaryship. As a politician Mr Huskisson belonged to that party of which Mr Canning was the head, and which first assumed a distinct character in 1809, when the latter statesman proclaimed his difference from Lord Castlereagh, and left the ministry. Mr Huskisson retired along with him, and continued to follow in that middle course which Mr Canning pursued, voting with ministers upon questions of general policy both foreign and domestic, but contending, with the opposition, for the necessity of retrenchment in the public expenditure. Being placed on the celebrated Bullion Committee, Mr Huskisson published an able pamphlet on the subject, entitled *The Question concerning the Depreciation of our Currency stated and examined.* In this tract Mr Huskisson defended the principles embodied in the report of the committee, and showed the necessity of the bank resuming cash payments. He afterwards took a prominent part in various debates on finance, in all of which he was listened to by the house with the greatest attention. In 1812 he obtained the lucrative situation of colonial agent for Ceylon; and in 1814 he was sworn a privy councillor, and appointed the first commissioner of woods and forests. His subsequent efforts in parliament were characterized by that middle course of policy which he had hitherto followed. On Mr Canning's appointment as secretary of state in 1822, and his declining to be re-elected for Liverpool, Mr Huskisson was chosen as his successor. In the following year he was appointed treasurer of the navy, and afterwards president of the board of trade. The part which Mr Huskisson took in the great questions brought before parliament from the year 1820 till the close of his life, will be found fully detailed in the article Britain. In the ministry of Lord Goderich he became secretary for the colonies, which post he retained under that of the Duke of Wellington; but having voted against government on a question of importance, he placed his office at the duke's disposal, and his resignation was accepted. His death took place on the 15th of September 1830. Being present at the opening of the Liverpool and Manchester railway, he came inadvertently in the line of one of the carriages, moving at a rapid rate, and the vehicle having passed over one of his legs, lacerated it in such a dreadful manner that he died soon after. The speeches of Mr Huskisson are characterized by little of that which in ordinary language is called eloquence. They are distinguished for clear, distinct statement, lucid arrangement, close adherence to the matter in hand, continuous reasoning, and a thorough knowledge of the subject discussed, in all its bearings and details. The strength of his oratory lay in the soundness and comprehensiveness of his views, particularly in all questions of political economy and commercial legislation. On such subjects he rose far above the majority of his parliamentary contemporaries, both in the extent of his information, and in the scientific character of his reasoning. He was, indeed, one of the few practical statesmen who could deal alike with matters of detail and the principles of the science by which they are illustrated. No debater ever came better prepared with facts and details bearing directly upon his subject, of which he always made himself completely master. His speeches are therefore exceedingly instructive, as well for their facts as for their reasonings. A collection of them was published in 1831, in three vols. 8vo. (R. R. R.)

HUSSARS, a term which originally signified the national cavalry of Hungary and Croatia, a species of light horse, which acted as irregular troops, and in that capacity were found highly serviceable. Hussars were first introduced into the French service in 1692, when they were formed on the model of the Hungarian cavalry, which had been subsidised by France before the reign of Louis XIII. In all the European armies of the present day, hussars are light horse, and differ from light dragoons only in some peculiarities of dress and equipment.

HUSSEINPOOR, a town of Hindustan, in the province of Delhi and district of Bareily, sixty-five miles east from Delhi. Long. 78. 13. E. Lat. 28. 44. N.

HUSSENABAD, a town of Hindustan, in the province of Khandesh, and belonging to the Mahrattas. It is situated on the south side of the Nerbuddah, sixty miles south from Bilsah. Long. 77. 53. E. Lat. 23. 40. N.

HUSSITES, in *Ecclesiastical History*, a party of reformers, the followers of John Huss. The person from whom the Hussites take their name was born in a little village in Bohemia, called Huss, and lived at Prague in the highest reputation, both on account of the sanctity of his manners and the purity of his doctrine. He was distinguished by his uncommon erudition and eloquence, and discharged at the same time the functions of professor of divinity in the university, and of ordinary pastor in the church of that city. He adopted the sentiments of Wickliffe, and the Waldenses; and in the year 1407 began openly to oppose and preach against various errors in doctrine, as well as corruptions in point of discipline, which then prevailed in the church. Huss likewise endeavoured to the utmost of his power to withdraw the university of Prague from the jurisdiction of Gregory XII., whom the kingdom of Bohemia had hitherto acknowledged as the true and lawful head of the church. This occasioned a violent quarrel between the incensed Archbishop of Prague and the zealous reformer, which the latter inflamed and augmented from day to day by his pathetic exclamations against the court of Rome, and the corruptions that prevailed amongst the sacerdotal order.

But there were other circumstances which contributed to inflame the resentment of the clergy against him. He adopted the philosophical opinions of the realists, and vehemently opposed and even persecuted the nominalists, whose number and influence were considerable in the university of Prague. In the year 1408 he also increased the bitterness of his enemies, by procuring a sentence in favour of the Bohemians, who had disputed with the Germans concerning the number of suffrages which their respective nations were entitled to in all matters that were carried by election in this university. In consequence of a decree obtained in favour of the former, which restored them to their constitutional right of three suffrages, usurped by the latter, the Germans withdrew from Prague, and, in the year 1409, founded a new academy at Leipsic. This event had no sooner happened than Huss began to inveigh with greater freedom than he had before done against the vices and corruptions of the clergy, and to recommend, in a public manner, the writings and opinions of Wickliffe, as far as these related to the papal hierarchy, the despotism of the court of Rome, and the corruption of the clergy. Hence, in the year 1410, an accusation was brought against him before the tribunal of John XXIII. by whom he was solemnly expelled from the communion of the church. Notwithstanding this sentence of excommunication, he proceeded to expose the errors and vices of the Roman Catholic church, with a fortitude and zeal that were almost universally applauded.

This eminent man, whose piety was equally sincere and fervent, though his zeal was perhaps too violent, and his prudence not always circumspect, was summoned to appear before the council of Constance. Secured, as he apprehended, from the rage of his enemies by the safe-conduct granted him by the Emperor Sigismund for his journey to Constance, his residence in that place, and his return to his own country, John Huss obeyed the order of the council, and appeared before it to demonstrate his innocence, and to prove that the charge of his having deserted the church of Rome was entirely groundless. However, his enemies so far prevailed, that by a scandalous breach of public faith he was cast into prison, declared a heretic because he refused to plead guilty, in obedience to the orders of the council, and burned alive in 1415; a punishment which he endured with unparalleled magnanimity and resignation.

The same unhappy fate was reserved for another reformer, Jerome of Prague, his intimate companion, who attended the council in order to support his persecuted friend. Jerome, indeed, was terrified into temporary submission; but he afterwards recovered his fortitude, and maintained the opinions, which he had for a while deserted through fear, amidst the flames, in which he expired in 1416.

The disciples of Huss adhered to their master's doctrine after his death with a zeal which broke out into an open war, that was carried on with the most unparalleled barbarity. John Ziska, a Bohemian knight, in 1420 put himself at the head of the Hussites, who had now become a considerable party, and threw off the yoke of Sigismund, who had treated their brethren in the most cruel and barbarous manner. In the year 1424, Ziska was succeeded by Procopius. The acts of barbarity committed on both sides were shocking and horrible; for notwithstanding the irreconcilable opposition between the religious sentiments of the contending parties, they both agreed in this one detestable principle, that it was innocent and lawful to extirpate by fire and sword the enemies of the true religion; and as such they reciprocally considered each other. But, by the interference of the council of Basil, in the year 1433, these commotions in a great measure subsided, and peace was at length restored. The Hussites, who were divided into two parties, viz. the Calixtines and Taborites, spread over all Bohemia and Hungary, and even Silesia and Poland; and some remains of them still subsist in those parts.

HUSTINGS (from the Saxon word *hustinge*, meaning *concilium* or *curia*), a court held in Guildhall before the lord mayor and aldermen of London. This court is very ancient, as appears by the laws of Edward the Confessor. Some other cities have likewise had a court bearing the same name, as Winchester and York. But this term is now applied to those temporary structures where the business of elections is conducted.

HUSTNAPORE, or HUSTINAGARA, formerly one of the most ancient and famous cities of Hindustan, in the province of Delhi, and for ages the capital of a powerful Hindu dynasty, of which the remote history is involved in obscurity. It was founded by Rajah Hasti, and is much celebrated in the Hindu mythological poems. This city has long been in ruins, and is now covered with large ant-hills. It is about twenty miles south-west from Daranagur, on a branch of the Ganges, formerly the bed of that river. Long. 77. 56. E. Lat. 29. 7. N.

HUSUM, a city of Denmark, in the province of Sleswick, the capital of a bailiwick of its own name, at the mouth of the river Hever. It contains several public buildings, 800 houses, and 3700 inhabitants, and was, during one period of the revolutionary war, from being neutral, converted into a place of great trade in colonial produce, which was conveyed from the stores in Heligoland, and distributed over the continent by smugglers. Long. 9. 6. E. Lat. 54. 32. N.

HUSZK, a market-town of the circle of Marmaros, in the province of Hither Theiss, in Hungary, composed of two parts, Koszeg and Boryana, containing a Catholic, a Unitarian, and a Reformed church, and 4200 inhabitants. Long. 23. 42. 42. E. Lat. 43. 9. 11. N.

HUTCHESON, DR FRANCIS, an eminent philosopher, was the son of a dissenting minister in the north of Ireland, and was born on the 8th of August 1694. He early discovered a superior capacity; and having gone through a school education, began his course of philosophy at an academy, whence he removed to the university of Glasgow, where he applied himself to the study of literature, in which his progress was commensurate with his uncommon abilities.

He then returned to Ireland, and having entered into the ministry, was just about to be settled in a small congregation of dissenters in the north of Ireland, when some gentlemen near Dublin, who knew his great abilities and virtues, invited him to open a private academy in that city. He complied with this invitation, and met with entire success. He had been established but a short time in Dublin, when his singular merits and accomplishments made him generally known; and his acquaintance was sought by men of all ranks who had any taste for literature, or any respect for learned men. Lord Viscount Molesworth is said to have taken great pleasure in his conversation, and to have assisted him with his criticisms and observations upon his Inquiry into the Ideas of Beauty and Virtue, before it was published. He received the same favour from Dr Synge, bishop of Elphin, with whom he also lived in close friendship. The first edition of this work appeared without the author's name, but the merit of the performance was such that he could not long remain concealed. So great was the reputation of the work, and the ideas it had raised of the author, that Lord Granville, who was then lord lieutenant of Ireland, sent his private secretary to inquire at the bookseller's for the author, and when he could not learn his name, he left a letter to be conveyed to him; in consequence of which Hutcheson soon became acquainted with his excellency, and was treated by him, all the time he continued in the government, with distinguished marks of favour and esteem.

From this time his acquaintance began to be still more courted by men of distinction, whether for station or for literature, in Ireland. Archbishop King, the author of the well-known book *De Origine Mali*, held him in high esteem; and the friendship of that prelate was of great use to him in screening him from two different attempts made to prosecute him for daring to take upon him the education of youth, without having qualified himself by subscribing the ecclesiastical canons, and obtaining a license from the bishops. He also enjoyed a large share in the esteem of the primate Boulter, who through his influence made a donation to the university of Glasgow, of a yearly fund for an exhibitioner, to be bred to any of the learned professions. A few years after the publication of his Inquiry into the Ideas of Beauty and Virtue, his Treatise on the Passions was published. Both these works have often been reprinted, and always admired for the sentiment and language, even by those who have not assented to the philosophy they teach, nor allowed it to have any foundation in nature. About this time he wrote some philosophical papers accounting for laughter, in a way different from that suggested by Hobbes, and more honourable to human nature; which papers were published in the collection called *Letters of Hibernicus.*

After he had taught in a private academy at Dublin for seven or eight years with great reputation and success, he was in the year 1729 called to Scotland to become professor of ethical philosophy in the university of Glasgow. Several young gentlemen came along with him from the academy, and his high reputation drew many more thither both from England and Ireland. Here he spent the remainder of his life, in a manner highly honourable to himself, and ornamental to the university of which he was a member. His time was divided between his studies and the duties of his office, except what he allotted to friendship and society. A firm constitution, and a pretty uniform state of good health, except some few slight attacks of the gout, seemed to promise a long life; yet he did not survive the fifty-third year of his age. He was married, soon after his settlement in Dublin, to Mrs Mary Wilson, a gentleman's daughter in the county of Longford, by whom he left one son, Francis Hutcheson, doctor of medicine, who published, from the original manuscript of his father, A System of Moral Philosophy, in three books, by Francis Hutcheson, LL. D. Glasgow, 1755, in two volumes 4to. See the Dissertations prefixed to this Work by Mr Dugald Stewart and Sir James Mackintosh.

HUTCHINSON, John, a philosophical writer, whose notions have made no inconsiderable noise in the world, was born in 1674. He served the Duke of Somerset in the capacity of steward, and in the course of his travels from place to place employed himself in collecting fossils. We are even told that the large and noble collection bequeathed by Dr Woodward to the university of Cambridge was actually made by him, and even unfairly obtained from him. When he left the duke's service to indulge his studies with more freedom, the duke, then master of the horse to George I. made him his riding surveyor, a kind of sinecure place of L.200 a year, with a good house in the Meuse. In 1724 he published the first part of Moses's *Principia*, in which he ridiculed Dr Woodward's Natural History of the Earth, and attacked the doctrine of gravitation established in Newton's *Principia*. In 1727 he published a second part of Moses's *Principia*, containing the principles of the Scriptural Philosophy. From this time till his death he published a volume every year or two, which, with the manuscripts he left behind him, were published in 1748, in twelve vols. 8vo. On the Monday before his death, Dr Mead urged him to be bled, saying pleasantly, "I will soon send you to Moses," meaning to his studies; but Mr Hutchinson taking it in the literal sense, answered in a muttering tone, "I believe, doctor, you will," and was so displeased that he dismissed him for another physician, but he died in a few days afterwards, on the 28th of August 1737. Singular as his notions appear, they are not without some defenders, who have obtained the appellation of *Hutchinsonians*. The reader may find a distinct and comprehensive account of the Hutchinsonian system in a book entitled *Thoughts concerning Religion*, printed at Edinburgh in 1743; and in a letter to a bishop, annexed to it, first printed in 1732.

HUTTANY, a town of Hindustan, in the Mahratta territories, and province of Bejapoor. It is large and populous, and has an extensive commerce with Bombay, Surat, Rachore, &c. It possesses a small stone citadel, and is enclosed with a rampart and a ditch. It has also a large and excellent place of accommodation for travellers, built of free stone, which is capable of lodging 500 travellers. It formerly belonged to the Mahommedan king of Bejapoor, but was taken by the Mahrattas about the middle of the seventeenth century. It was retaken by the Mahommedans in 1679, when many of the inhabitants were carried into captivity and sold as slaves. After the death of Aurungzebe it again fell into the hands of the Mahrattas. Long. 75. 20. E. Lat. 16. 59. N.

HUTTON, Dr James, physician and naturalist, was the son of Mr William Hutton, a respectable merchant in Edinburgh. He was born on the 3d of June 1726, and having lost his father while he was very young, the charge of his education devolved on his mother, who determined that it should be very liberal. Having finished his grammar-school education at the high school of Edinburgh, he entered the university at the age of fourteen, in the year 1740. He always considered himself as greatly indebted to Professor Stevenson's lectures on logic, not because they made him a logician, but because they accidentally gave him a predilection for chemistry, which he retained and cherished to the close of life. As an illustration of some particular doctrine, the professor observed, that whilst the acids can singly dissolve the baser metals, they must unite their strength before they can have any influence upon gold; that metal is only to be dissolved by nitro-muriatic acid, formerly denominated *aqua regia*. From this remark he found his thirst for chemical knowledge daily increase, and sought for information from every quarter.

He always evinced talents sufficient to encourage the prosecution of his studies; but it was the wish of his friends that he should turn his attention to business, and with this he complied, though contrary to his own inclinations. In 1743 he was put as an apprentice to Mr George Chalmers, writer to the signet, where he soon discovered the ruling propensity of his mind; for when he should have been transcribing law papers, he was amusing his fellow apprentices with experiments in chemistry. Mr Chalmers perceiving this, generously freed him from his obligations to serve him, desiring him to turn his attention to some other employment more congenial to his views. He fixed his choice on the study of medicine, as nearly related to his favourite pursuits; and after spending about three years at Edinburgh, he studied two years at Paris; and returning home by the Low Countries, took his degree of doctor of medicine at Leyden, in September 1749. The subject of his thesis was, *De Sanguine et Circulatione in Microcosmo.*

When he arrived in London, about the end of 1749, he conceived the design of settling in the world. He justly conjectured that Edinburgh did not hold out for him any flattering prospects in the capacity of physician, as the principal practice was in the hands of a few eminent physicians who had been long established. He accordingly wrote to his friends in Edinburgh with much anxiety as to the subject of his future prospects in life. To Mr James Davie, a young man of nearly his own age, with whom he contracted a friendship which death only could extinguish, he also communicated the perplexed state of his mind. Their mutual knowledge of the nature of sal-ammoniac led them to establish this manufacture, which afterwards became a most lucrative concern to both. The sentiments of Mr Davie were communicated to Dr Hutton while yet in London, which probably was the chief reason why he resolved to abandon entirely the practice of physic.

On his return to Edinburgh, in the year 1750, he resolved to devote all his attention to agriculture, which might probably be occasioned by his having succeeded to a small property in Berwickshire on the death of his father. Professor Playfair of the university of Edinburgh has ascribed it, and we apprehend with great propriety, to the native simplicity of his character, and the moderation of his views, which were always free from ambition. His attachment to the life of a farmer was increased by his acquaintance with Sir John Hall of Dunglass, a gentleman who was very ingenious, a friend and lover of science, and one who well understood agriculture. Determined

Hutton.

to make himself master of rural economy, Dr Hutton went into the county of Norfolk, where he continued for some time in the house of a farmer, who was at once his preceptor and his host. The farmer's name was John Dybold, whose practical knowledge of agriculture Dr Hutton always mentioned in terms of the highest respect.

During his residence in this county, which was to him a paradise, he made frequent excursions into different parts of England; and although information respecting rural economy was the great and primary object of his pursuit, yet it was here that he first commenced the study of mineralogy, to serve him as an amusement on the road. He acquainted his friend Sir John Hall that he had become remarkably fond of studying the surface of the earth, and was narrowly examining every pit, or ditch, or bed of a river that fell in his way. The agricultural knowledge he acquired in Norfolk increased his desire to pay a visit to Flanders, the only place in Europe where husbandry can boast of very great antiquity. He set out accordingly in the spring of 1754, and returned to England during the summer of the same year. Soon after his arrival in London he observed, in a letter to Sir John Hall, "had I doubted of it before I set out, I should have returned fully convinced that they are good husbandmen in Norfolk."

About this time he returned to his native country, and was for some time at a loss what place to fix upon for the purpose of carrying into effect his agricultural improvements. His own farm at length became his choice, and a ploughman whom he had brought with him from Norfolk gave the first specimen of excellent tillage ever exhibited in that part of Scotland. To Dr Hutton the country is indebted for the introduction of the new husbandry into a county where it may be said to have made more astonishing progress than in almost any other part of the British empire. In the year 1764 he made an excursion into the north of Scotland, in company with Commissioner, afterwards Sir George Clerk, a man of singular worth and abilities. They proceeded to Crieff, Dalwhinnie, Fort Augustus, and Inverness, and returned along the coast by Aberdeen to Edinburgh. To increase his knowledge of geology was Dr Hutton's chief aim in this tour, to which he had now determined to pay the most unremitting attention. About the year 1768 he devoted his whole time to scientific pursuits, and having met with a favourable opportunity of letting his farm to advantage, he took up his residence in Edinburgh. He now turned his attention very much to the study of chemistry, and we believe he was the first who discovered that mineral alkali is contained in zeolite. The same fact has since been confirmed by the experiments of that celebrated mineralogist M. Klaproth, as well as by those of Dr Kennedy, which have led to others of a similar nature.

Dr Hutton gave to the world his first publication in 1777, which was a small pamphlet of thirty-seven pages, entitled *Considerations on the nature, quality, and distinctions of Coal and Culm.* It was designed to answer a question which began to be much agitated, whether the small coal of Scotland is the same with the culm of England; and whether it ought to be carried coastwise free of all duty. This created a keen contest between the proprietors and revenue officers, the one insisting that it should, and the other that it should not pay any duty. It was discussed before the board of customs in Scotland, and even occupied the attention of the privy council. The small coal of Scotland was finally exempted from the payment of duty, to which the pamphlet of Dr Hutton greatly contributed.

During a period of thirty years the attention of the doctor was turned towards geological studies, to qualify him for writing on his favourite topic, a new theory of the earth. Long before that theory made its appearance in the world, he had completed the outline of it, which, however, was shown only to a few confidential friends. He was first induced to publish it by communicating an abridgment of it to the Royal Society of Edinburgh. Of the merits or defects of this celebrated theory this is not the place to speak. It found a very able advocate in Professor Playfair, whose Illustrations must ever be regarded as one of the finest specimens of philosophical writing that our language can boast of.

Huygens

A theory of rain from the same author appeared in the first volume of the Edinburgh Transactions. He had made meteorology his study for a considerable time; and his theory has been pronounced one of the few to be met with in that department of knowledge which is deserving of consideration. Soon after this publication, Dr Hutton gave the world, in three volumes quarto, An Investigation of the Principles of Knowledge, and of the Progress of Reason from Sense to Science and Philosophy. This work never attracted any notice. His elements of agriculture, the result of much study and long experience, was the last work which he seemed anxious to publish; but it was left in manuscript at his death, which took place in 1797.

To the name of philosopher Dr Hutton was most justly entitled, by reason of his natural talents, acquisitions, and temper. The direction of his studies was rather uncommon and irregular; but for that very reason it was peculiarly fitted to develope that quick penetration and originality of thought, by which his intellectual character was strikingly marked. The greatest acquisitions of wealth and fortune never excited more lively sensations of pleasure in the minds of men, than those which arose in the mind of Dr Hutton on hearing of a new invention, or on being made acquainted with a new truth. This pleasure, which appeared almost ridiculous to those who could not enter into his views, was not confined to any one branch of science; for, in the language of Professor Playfair, "he would rejoice over Watt's improvements on the steam-engine, or Cook's discoveries in the South Sea, with all the warmth of a man who was to share in the honour or the profit about to accrue from them." Dr Hutton was not exclusively attached to the company of men of letters, whose conversation was entirely directed to subjects of literature; for he could occasionally unbend himself, and enjoy the innocent hilarity of promiscuous company, when he freely indulged in the gratification of his native pleasantry. An admirable account of his life, written by Professor Playfair, was published in the Transactions of the Royal Society of Edinburgh.

HUY, a town of the Netherlands, in the province of Liege, the capital of a circle of the same name. It has a very strong fortress, commanding the passage over the river Meuse, to which the great road leads. It is surrounded with vineyards, and is the seat of some manufactures, and it contains 800 houses, with 5647 inhabitants. Long. 4. 12. E. Lat. 50. 31. N.

HUYGENS de Zuylichem, Christian, lord of Zeelhem, was the second son of Constantine Huygens, secretary and counsellor to the princes of Orange, and born at the Hague on the 14th of April 1629. He was one of those rare men who, from the most subtile theories, know how to deduce the most useful applications, and whom admirable inventions in the arts, as well as the sciences, place on the same level with the Archimedeses and the Newtons. His family, originally from Brabant, was rich and respected; and the important post which his father held under three successive princes of Orange had been filled by his grandfather, as it subsequently was by his elder brother Constantine, who in this capacity attended King William in the celebrated expedition to England, which issued in the Revolution of 1688. His father, a distinguished man of letters, whose poetical compositions had attained much celebrity, was not slow in remarking the happy qualities of his genius, and, full of paternal solicitude for his improvement, became his first instructor. He early taught his son music, arithmetic, and geography; and, about the age of thirteen, initiated him in the knowledge of mechanics, for which young Huygens showed a surprising aptitude. At fifteen he received the assistance of a master in the mathematics, a geometer of Amsterdam named Stampioen, of whom Descartes has left an unfavourable impression, but who in a short time enabled his pupil to make great progress. At the age of sixteen he was sent to Leyden to study law under the learned jurisconsult Vinnius, who dedicated to him his Commentary on the Institutions; but he did not permit jurisprudence to divert him from his mathematical studies, which he prosecuted at this place, as well as afterwards at Breda, where an university had been erected, and where, being placed under the direction of his father, he resided from 1646 to 1648. In these two cities he had as masters two very able geometers, Francis Schooten and John Pell; and his first essays were so successful that they attracted the notice of Descartes, to whom the author had communicated them. The genius of this great man divined instinctively that of Huygens. "It is some time," said he, in a letter written at this period, "since Professor Schooten sent me a writing by the second son of M. de Zuylichem touching a mathematical invention which he had attempted to make; and although he has not yet found his account in the pursuit (which is not wonderful, seeing he sought a thing which no one has ever been able to find), yet he has taken such a bias towards geometry, that I feel assured he will become excellent in that science, of which I scarcely see any one who knows any thing." On his part, the young geometer was filled with admiration of the great philosopher; and he wrote to Father Mersenne that, for ages, no one comparable to him had appeared. Nevertheless, Huygens had not the good fortune to see him. Descartes had quitted Holland, and when, in 1649, Huygens, having left the university, travelled with Henry Count de Nassau, he regretted much not having it in his power to pass from Denmark to Sweden, whither Descartes had repaired, out of complaisance to the imperious Christina. After this tour, he settled in his native country; and it was then that he commenced that series of inventions which have rendered his name so justly celebrated. In 1651 he published at Leyden his *Theoremata de quadratura Hyperboles, Ellipsis, et Circuli, ex dato portionum gravitatis centro*; a work which afforded a favourable specimen of his genius for mathematics, and gave promise of still greater excellence. In 1655 he travelled into France, and took the degree of doctor of laws at Angers. In 1658 he published at the Hague his *Horologium oscillatorium, sive de motu pendulorum*. In a preceding work, entitled *Brevis Institutio de usu Horologiorum ad inveniendas longitudines*, he had exhibited a model of a newly-invented pendulum; but as some persons, envious of his reputation, laboured to deprive him of the honour of the invention, he wrote his *Horologium oscillatorium* to explain the construction of his pendulum, and to show that it differed from the astronomical pendulum invented by Galileo. In 1659 he published his *Systema Saturninum, sive de causis mirandorum Saturni phænomenôn, et comite ejus planeta novo*. Galileo had endeavoured to explain some of the appearances exhibited by the planet Saturn; he had at first perceived two attendant stars, but some time afterwards was surprised to find that they had disappeared. Huygens, desirous to account for these changes, laboured with his brother Constantine to improve the construction of telescopes; and having at length made an instrument of this kind, possessing greater power than any which had yet been contrived, he proceeded to observe the phases of Saturn, and to record all the different aspects of that planet. The results were of equal interest and importance to the science of astronomy. He discovered a satellite of that planet, which had hitherto escaped the notice of astronomers; and, after a long course of observation, he showed that the planet is surrounded with a solid and permanent ring, which never changes its situation. In 1660, he took a second journey into France, and the year following he visited England, where he communicated the art of polishing glasses for telescopes, and was admitted as a member of the Royal Society. The air-pump, then recently invented, he materially improved; and about the same time he also discovered the laws of the collision of elastic bodies, as did afterwards our own countrymen, Wallis and Wren, who disputed with him the honour of the discovery. After a stay of some months in England, Huygens returned to France, where, in 1663, his merit became so conspicuous, that Colbert resolved to bestow on him such a pension as might induce him to establish himself at Paris. But this resolution was not carried into effect until 1665, when letters written in the king's name were forwarded to the Hague, where he then resided, inviting him to repair to Paris, and offering him a considerable pension, with other advantages. Huygens accepted the proposal of the French minister, and, from 1666 to 1681 resided at Paris, where he was admitted as a member of the Royal Academy of Sciences. During this period he was occupied with mathematical pursuits; he wrote and published several works, which were most favourably received; and he invented and perfected some useful instruments and machines. But, by continued application, his health began to be impaired; and although he had twice had recourse to his native air, and on both occasions derived benefit from the change, the improvement was only temporary, and he at length found it necessary to quit France and return to his own country. It is not improbable that his departure was accelerated by the revocation of the edict of Nantes; for although he had received an assurance that he would be permitted to enjoy the same liberty as before, without being molested on account of his opinions, he had but little encouragement to remain in a country where his religion was proscribed, and those who professed it subjected to the most cruel persecution. He accordingly left Paris in 1681; passed the remainder of his life in his own country, occupied with his usual pursuits; and died at the Hague on the 8th of June 1693, in the sixty-seventh year of his age, whilst his *Cosmotheoros*, a treatise on the plurality of worlds, was passing through the press. The *Opera Varia* of Huygens were published in 1700, 4to, and his *Opuscula Posthuma* appeared soon afterwards, Leyden, 1703, in 4to. The former collection, which is generally bound in four volumes, contains the greater number of the pieces which he published separately, and is divided into four parts; the first comprising the pieces relating to mechanics; the second, those relating to geometry; the third, those relating to astronomy; and the fourth, miscellaneous productions, which could not be arranged under any of the preceding heads. 'sGravesande had the care of this edition, in which he inserted various additions to the different pieces extracted from the manuscripts of Huygens. The same individual also superintended the publication of his *Opera Reliqua*, which appeared at Amsterdam in 1728, in two vols. 4to, and contain, 1. his Treatises on Light and Gravity; and, 2. his *Opuscula Posthuma*, originally printed in 1703. For a masterly account of the genius and labours of Huygens, the reader may consult the Dissertations by Professors Playfair and Sir John Leslie, prefixed to this work. This illustrious man gave his whole time to science; he loved a quiet studious life, and found sufficient enjoyment in pursuing curious and useful researches. He was modest, amiable, cheerful, and in all respects as estimable in private life as he was eminent in science. It is not a little singular, that the discovery of the real nature, or at least of the true figure, of the luminous belt or ring which encompasses the planet Saturn should have been made by the same individual who invented the pendulum clock and the micrometer. (A.)

HUYSUM, the name of several Dutch painters. The most celebrated of these was John, whose subjects were flowers, fruit, and landscapes. He was born at Amsterdam in 1682, and was a disciple of Justus van Huysum, his father. He set out in his profession with a most commendable principle, not so much to paint for the acquisition of money, as of fame; and therefore he did not aim at expedition, but at delicacy, and strove, if possible, to arrive at perfection in his art. Having studied the pictures of Mignon, and all other artists of distinction who had painted in his own style, he tried which manner would soonest lead him to imitate the beauties of each flower, fruit, or plant, and then fixed upon a manner peculiar to himself, and which seems almost inimitable. His pictures are finished with inconceivable truth; for he painted every thing after nature, and was so singularly exact as to watch even the hour of the day in which his model appeared in its greatest perfection. By some persons he was thought to paint with greater freedom than Mignon or Breughel; with more tenderness and nature than Mario da Fiori, Michel Angelo di Campidoglio, or Segers; with more mellowness than De Heem; and with greater force of colouring than Baptist. At length his reputation rose so high, that he fixed immoderate prices on his works; so that none but princes, or those possessed of princely fortunes, could pretend to become purchasers. The large sums which Van Huysum received for his works caused him to redouble his endeavours to excel; no person was admitted into his room whilst he was painting, not even his brothers; and his method of mixing the tints, and preserving the lustre of his colours, he kept an impenetrable secret. From the same principle, he would never take any disciples, excepting one lady, named Haverman; and he even grew envious of her merit. By several domestic disquiets his temper became changed, and he grew morose, fretful, and apt to withdraw himself from society. There were many who envied his fame, but he continued to work, and his reputation never diminished. It is universally agreed that he excelled all who painted fruit and flowers before him, by the superiority of his touch, the delicacy of his pencil, and an amazing skill in finishing; nor does it appear probable that any future artist will ever become his competitor. Besides his merit as a painter of flowers, he also painted landscapes with great applause. They are well composed; and although he had never seen Rome, he adorned his scenes with the noble remains of ancient magnificence preserved in that city. His pictures in this style are well coloured, and every tree is distinguished by a touch that is proper for the leafing. The grounds are well broken, and disposed with taste and judgment; the figures are designed in the manner of Lairesse, highly finished, and touched with a great deal of spirit; and through the whole composition the scene represents Italy, in the trees, the clouds, and the skies. He died in 1749, at the age of sixty-seven.

HYACINTHUS, a son of Amyclas and of Diomede (Apollodor. iii. 10, 3), or of Pierus and of Clio (i. 3, 3), beloved by Apollo and Zephyrus. He gave the preference to the former, and whilst they were amusing themselves at quoit, Zephyrus in revenge blew the quoit which Apollo had thrown, on the forehead of Hyacinthus, and he was killed by the blow. Apollo was so disconsolate at the loss of Hyacinthus that he changed his blood into a flower of the same name, and on the petals engraved the exclamation Αι, *alas*. (Paus. iii. 19, 1.)

HYADES, nymphs, daughters of Atlas and Æthra (Ovid), of Erechtheus, king of Athens (Eurip.), of Hyas and Bæotia (Hygin.) Their number and names are uncertain, but generally they are either seven or six, and they are called, Cisseis, Nysa, Erato, Eriphia, Bromie, Polyhymno; or, if they are seven, Ambrosia, Eudora, Phæsole, Coronis, Polyxo, Phæo, Thyone. At their death they were changed into stars, and placed on the head of Taurus, one of the twelve signs of the zodiac. They were supposed to preside over rain (hence the name, from ὕω, *to rain*), because the rising and setting of the Hyades was always attended with much rain. (Ovid. *Fast.* 5, 165; Cic. *de Nat. Deor.* 43.) The Latins called them *suculæ*, swine, because they were so ignorant of the Greek language that they imagined the Greek word to be derived from ὗς, *a sow*. (Gell. xiii. 9. Plin. ii. 39.; xviii. 26.)

HYBLA, in *Ancient Geography*, called also MEGARA, which last name it took from the Megareans, who led thither a colony. In Strabo's time Megara was extinct; but the name *Hybla* remained on account of the excellent honey which takes its name from this place. It was situated upon the east coast of Sicily, between Syracuse and the Leontines. The *Hyblæi colles*, small eminences at the springs of the Alabus, near this place, were famous for their variety of flowers, and especially thyme; the honey gathered from which was by the ancients reckoned the best in the world, excepting that of Hymettus in Attica.

HYBRIDA PLANTA, a monstrous production of two different species of plants, analogous to a mule amongst animals. The seeds of hybrid plants will not propagate.

HYBRISTICA (of ὕβρις, *injuria*), in *Antiquity*, a solemn feast held amongst the Greeks, with sacrifices and other ceremonies, at which the men attended in the apparel of women, and the women in that of men, to do honour to Venus in quality either of a god or a goddess, or both. But, according to the account given by others, the hybristica was a feast celebrated at Argos, in which the women, being dressed like men, insulted their husbands, and treated them with all marks of superiority, in memory of the Argive dames having anciently defended their country with singular courage against Cleomenes and Demaratus. Plutarch speaks of this feast in his treatise of the great actions of women. The name, he observes, signifies infamy, and is well accommodated to the occasion, in which the women strutted about in men's clothes, whilst the men were obliged to dangle in petticoats.

HYDE, EDWARD (afterwards Earl of Clarendon), was born at Dinton, in the county of Wilts, on the 18th of February 1609. He was the third son of Henry Hyde, the descendant of a family of that name, which had resided from a remote period at Norbury, in Cheshire. Edward, after receiving his first education under his father's roof, was sent, at the age of thirteen, to Magdalen Hall, at Oxford. He was originally intended for the church; but, in consequence of the death of his last surviving elder brother, his destination was changed, whilst he was at the university, from the profession of the church to that of law, and in 1625 he was entered at the Middle Temple. A severe ague with which he was attacked that year caused a suspension of his studies, and temporary removal from the Middle Temple, to which he returned in 1626. In 1628, when riding the Norfolk summer circuit with his uncle, Sir Nicholas Hyde, chief-justice of the King's Bench, who died in 1631, he caught the small-pox; and his legal studies were again for a long time interrupted. He married, in 1629, a daughter of Sir George Ayliffe, who died of the small-pox six months afterwards. He married a second time in 1632, in which year he lost his father. His second wife was a daughter of Sir Thomas Aylesbury, Bart. master of requests; and by her he had many children. Hyde now applied himself to the study of the law with a diligence which he had not shown before, and his success soon surpassed the expectations of his contemporaries. Meanwhile he lived little with lawyers; but he had many associates of political and literary celebrity, Lord Falkland, Selden, Chillingworth, Waller the poet, Ben Jonson, May the historian, Hales, Sheldon, Earles, and Morley. To these may be added a few men of high rank, as the Marquis of Hamilton, the Earls of Pembroke, Holland, and Manchester, and Lord Coventry. In 1635, through an accidental circumstance, he also obtained the notice of Archbishop Laud. In the course of an inquiry into the state of the customs instituted by the primate in his capacity of commissioner of the treasury, Hyde was mentioned to him as one who had been much consulted by some aggrieved merchants, and could afford the information desired. From this time Laud saw him frequently, employed him upon many occasions, and caused him to be noticed and employed by others. From 1635 till 1640 may be regarded as the most fortunate period of Hyde's life. He was successful in his profession, possessed a competent private fortune, and was happily married. In 1640 he was elected member of parliament for Wootton-Basset and for Shaftesbury, and took his seat for the former. The parliament met on the 13th of April, and was dissolved on the 5th of May. Hyde's first brief parliamentary career was characterized by activity and an honest zeal in the correction of abuses, from which not all the friendship of Laud and the favour of the court was able to divert him. In his first speech he denounced the earl marshal's court, which, in its protection of the privileges of the titled classes, had been intolerably vexatious and oppressive; and he showed himself a true and practical friend of rational freedom. During this very short session, he served in seven committees. He foresaw the evil consequences of the hasty dissolution, and endeavoured in vain to prevail on Laud to employ his influence with the king to prevent it. In the next parliament, which met in November 1640, Hyde sat for Saltash. He recommenced his proceedings against the earl marshal's court, of which he procured the suppression. He was also chairman of a committee of inquiry into the abuses of the council of York, and the court of the council of the marches; and he conducted the impeachment of three of the barons of the exchequer for illegal exactions at the bidding of the crown. But Hyde, though zealous for the redress of grievances, was opposed to the encroachments of parliamentary authority, which began to assume a formidable aspect. Strongly attached to episcopacy, he also disliked the attempts of the parliament to remodel the government of the church; and boasts that as chairman of the committee on that question, he interposed so many delays that the project was suspended. He vehemently protested against the Commons' remonstrance, his opposition to which was the occasion of his first introduction to Charles I. He had written an answer to it, which he showed in confidence to Lord Digby. Digby made it known to the king, who sent for Hyde, requested the paper, approved, and published it as the reply of the king with the advice of his council. Soon afterwards the king offered to Hyde the office of solicitor-general, which the latter declined, alleging that he could better serve his sovereign in an unofficial capacity. To this the king assented; and meanwhile committed to him, to Lord Falkland, and to Sir John Colepepper, the entire management of his affairs in the House of Commons, assuring them that he would take no step therein without their concurrence. Notwithstanding this assurance, Charles, without apprizing these chosen councillors, not long afterwards had recourse to the ill-timed measure of attempting to seize the five members in the House of Commons. Though the consequences of this rash act were irretrievable, and the royal cause was almost hopeless, Hyde continued courageously to support it. During many months he was secretly employed in writing answers for the king to the declarations of the parliament, and had frequent interviews with him by stealth; but he was at length suspected, and narrowly escaped committal to the Tower by flying to the king at York. Though Hyde had thus become openly an adherent of the king, he long refused office. He declined the proffered post of secretary of state; and it was not till March 1643 that, on the promotion of Sir John Colepepper to the mastership of the rolls, he accepted the chancellorship of the exchequer. He was one of the commissioners at the negotiations at Uxbridge, where, as on other occasions, he fruitlessly laboured to effect peace between king and parliament, as far as was compatible with a preservation of the royal prerogative and the rights of the established church.

In 1644, after the battle of Naseby, Hyde was appointed, together with Sir John Colepepper and Lords Capel and Hopton, to form a council to attend, watch over, and direct the Prince of Wales. After hopelessly witnessing for many months a course of disastrous and ill-conducted warfare in the west, they fled with him, first to Scilly, and thence to Jersey; from which, at the entreaty of the queen, but against the opinion of Hyde and others of the council, the prince, in 1646, repaired to his mother at Paris, attended only by Sir John Colepepper, and leaving Hyde at Jersey. In this retreat Hyde remained till the spring of 1648, engaged in the composition of his history of the rebellion. He also wrote, during this period, an answer to a declaration of the parliament, in which they charged the king with all the evils which had happened, and justified the discontinuance of all further addresses to him. In May 1648, he was summoned to attend the prince, who, at the head of a fleet which had espoused the royal cause, was blockading the Thames. Hyde, after encountering sundry difficulties, and amongst others seizure by privateers off Ostend, did not meet the prince till his return to the Hague, about the end of August, from his fruitless expedition. Hyde found dissensions in the prince's little court at the Hague, especially between Prince Rupert and Lord Colepepper. The news of the death of Charles I. for a while afflicted and appalled them; but their animosities soon broke out afresh, and disturbed the councils of the new sovereign. In 1649, at the suggestion of Lord Cottington, Hyde and that nobleman were sent as ambassadors to the court of Spain for the purpose of soliciting its assistance. They were coolly received, and had the mortification of perceiving that the Spanish court was more inclined to cultivate the friendship of the commonwealth of England; and to the memorial which they presented to the king of Spain in a private audience, they obtained only a cold and ambiguous reply. The treatment they experienced from the Spanish government was meanly time-serving, and varied with the fortune of Charles's affairs. On his determining to proceed to Scotland, upon the invitation of the Scotch council and parliament, the ambassadors were treated with more regard. Upon the news of Cromwell's victory over Argyll's army, they were desired to depart. Accordingly, Hyde quitted Spain, unaccompanied by his colleague Lord Cottington, who chose to remain as a private person, though not permitted to reside at Madrid. On Hyde's return from Spain in 1651, he met at Paris the king, returned from the ill-fated expedition which terminated in his defeat at Worcester; which rash interference, and the king's negotiation with the Scotch, and acceptance of the covenant, Hyde severely censured. He found himself exposed to the enmity of many, especially of the queen. Sundry calumnies were circulated against him, and two petitions were prepared, one from presbyterians, the other from papists, praying his removal from Charles's councils. But Charles's confidence in Hyde was not shaken by these intrigues; and he appears to have seen their groundlessness, and properly appreciated the valuable services of so honest, able, and zealous a minister. Extreme poverty was amongst the evils which, in a greater or less degree, since Hyde's departure from Jersey, he and his family had been compelled to bear. His family resided principally at Antwerp, and he and they were almost reduced to want the most common necessaries of life; yet his courage and integrity never faltered, and he would not even (as many had done) compound for his estates in England, lest thereby he should seem to acknowledge the existing government. Year after year, too, the hope of relief to the royalist party from foreign aid was waning away; and neither foreign war nor domestic conspiracy seemed to avail against the power of Cromwell. In 1658 Cromwell died, but the protectorate passed, like an inheritance, into the hands of his son; and though the hopes of the royalists were naturally excited, the prospects of restoration were still found to be dark, vague, and distant. Hyde, who was now lord chancellor, corresponded much with those whom the weakness of Richard Cromwell and the distracted state of England had rendered favourable to the royal cause, and proved instrumental in forwarding that Restoration which was at length more ostensibly effected by the powerful agency of Monk.

The period immediately following the Restoration was that of Hyde's greatest power. He was the first minister, presiding over a cabinet in which the principal offices were filled by his friends (for such were Sir Edward Nicholas, the Earl of Southampton, and the Marquis of Ormonde), and the principal measures of the government were peculiarly his. The first great measure of his administration was the act of indemnity. This was in accordance with the king's declaration from Breda, in which he promised pardon to all his subjects, save such as should be excepted by parliament, by which was intended the exclusion of those who had been instrumental to his father's death. The lord chancellor was on the side of mercy, and urged the speedy adoption of this healing measure on a reluctant and vindictive parliament. In the settlement of property under the act of indemnity some apparent injustice was unavoidably committed, by the necessity of dealing differently, not according to the merits of persons, but the nature of the property to be dealt with, and the title by which it was held. Transactions between individuals could not be reached; but grants to or purchases by individuals from the usurping state became subject to revision from defect of title; and crown and church lands were recovered from their holders, whilst the impoverished royalist who had sold his property to support the cause of the king was doomed to see the sale confirmed, and himself debarred from compensation. The royalists consequently murmured loudly. They called the statute an act of "indemnity for the king's enemies, and of oblivion for his friends;" and they hated the chancellor for the part he took in framing this act, and his steady adherence to the principles of it. The next important measure was the settlement of the revenue. It is asserted by several authorities, that the chancellor might have obtained for the king from the parliament, in the first fervour of their revived loyalty, an annual revenue of L.2,000,000. But it was not his wish to render the sovereign independent of the aid of his parliament, and he therefore sought for him only L.1,200,000, a sum scarcely sufficient for the exigencies of the state, unless administered with due economy. This sum the parliament readily granted. Military tenures, and the oppressive privileges of wardship, purveyance, and pre-emption, were abolished, and the excise on liquors was granted in their stead. The restoration of the bishops to the House of Lords, the statute against tumultuous petitioning, the vesting of the supreme command of the militia solely in the crown, and the repeal of the triennial acts, were measures promoted by the chancellor for the purpose of strengthening the prerogative of the crown. In the regulation of the judicature he deserved high praise. He showed a rare impartiality and discernment in his appointments, and eminent integrity and diligence in the administration of his own office. His conduct in ecclesiastical matters was less liberal and judicious. He believed episcopacy to be the only form of church government suitable to monarchy, and was too little tolerant towards other sects. Under his administration several oppressive acts were passed; the act of uniformity, compelling clergymen, on pain of abandoning their livings, to subscribe to the forms of the church of England, and to the doctrine of passive obedience, by which two thousand were ejected; the act against conventicles, imposing fines on all present at any meeting for religious worship at which five assisted besides the family; and the five-mile act, by which dissenting teachers who had not taken the oath of passive obedience were forbidden to approach within five miles of a place where they had preached since the act of indemnity. But the sin of such oppressions lies chiefly with the parliament. In that which succeeded the convention parliament there were a great majority of high churchmen. Venners' insurrection had strengthened the prejudices against sectarians; and it is by no means certain that Clarendon could have stemmed the torrent of intolerance, even if he had wished or attempted to do so.

In 1660, on the 3d of September, his daughter Anne was secretly married to the Duke of York; an union which, after much opposition from the mother and sister of the duke, and the calumnies of profligate courtiers, was acknowledged about the end of the year. The discovery was received by the chancellor with violent demonstrations of indignation and grief. He seems to have been solicitous to repel the imputation of having secretly promoted an alliance so flattering to his ambition, and to have dreaded the effects of the jealousy it might excite. He had in the following year a share in negotiating a marriage for the king with Catherine of Portugal; a marriage which, when it proved unfruitful, was groundlessly supposed to have been promoted by Clarendon under that expectation, and with a view that his son-in-law or his descendants might inherit the throne. Such suppositions would have been far fetched, even if an incapacity in the princess to bear children had really existed; and it must fall to the ground when the contrary is known. Difference of religion was the only obvious objection to this alliance; but there was no Protestant princess to whom Charles would ally himself; and amongst Catholics the princess of Portugal was perhaps least objectionable, and conferred the advantages of a dowry of L.500,000, Tangiers, Bombay, and free trade with Portugal and its colonies. The profligacy of Charles, and the malign influence of Lady Castlemaine, afterwards Duchess of Cleveland, which Clarendon vainly endeavoured to resist, were the main causes of the unhappiness of this marriage.

Hyde showed no avidity for emoluments or distinctions. After the Restoration, when Monk was created a duke, and Montague an earl, Hyde declined a proffered peerage, resting his refusal on unwillingness to excite disaffection amongst the new supporters of monarchy by an apparent eagerness on the part of the king to load with honours his old adherents. When the marriage of his daughter with the Duke of York became known, this objection ceased; a public mark of the king's unaltered regard be-

Hyde.

came desirable, and Hyde accepted the barony of Hindon. A further elevation took place in 1661, at the coronation, on the request of the Duke of York; and the chancellor was created Earl of Clarendon, and took his seat as such on the 11th of May. At the time when he was made a baron he accepted a present of L.20,000 from the king; but he had declined at an earlier period the more valuable grant of ten thousand acres of crown land, which Charles was willing to bestow.

One of the measures of his administration which has exposed him to most reproach, was the sale of Dunkirk in 1662. Yet it cannot be shown that the motive was corrupt, or the measure indefensible. Money was wanted; large arrears had been due to the army; and large sums had been necessarily expended in military and naval stores. The revenue settled by the parliament was insufficient in amount, and with difficulty collected; and subsidies were granted by the parliament in 1661 as an additional aid. The wants of the state were still urgent. Dunkirk was a source of expense to the yearly amount of L.120,000. France was willing to purchase; and after much negotiation between Clarendon and D'Estrades, Dunkirk was sold to France for 5,000,000 livres. A more truly censurable act of Clarendon's administration was sanctioning the acceptance of money for Charles from Louis XIV. though he had the honesty to refuse it for himself, and laying the foundation of that secret correspondence which at length rendered the king of England almost the pensioned servant of France. The sale of Dunkirk tended to weaken the popularity of Clarendon with the nation. He soon began to lose the favour of the king, by his opposition, in July 1663, to a measure Charles had much at heart, namely, a bill to invest the king with a discretionary power of dispensing, for a fine, penal laws against all sects, by which Charles hoped to favour the Catholics, though this purpose was necessarily cloaked under a promise of toleration, including all Protestant dissenters. Clarendon, who knew and disapproved of the motive, vehemently opposed this bill, and caused it to be laid aside; and Charles from that time began to entertain a dislike of his minister, which the enemies of Clarendon sedulously fostered. The Duke of Buckingham and other chosen associates of the king tried to undermine the influence of Clarendon by mimicry and taunts, representing him as a churlish pedagogue, and inciting the king to emancipate himself from restraint. His influence as a minister was also lessened by the substitution of Bennet for his firm friend Sir Edward Nicholas, and by the reviving power of Coventry and Ashley. He also paid the penalty of power, in bearing the load of whatever calamities befel the nation. Even the plague, and the fire of London, and the disastrous issue of the Dutch war (a war to which the public was favourable, and he was adverse), concurred to weaken his popularity. The defenceless state of the Thames, which enabled the Dutch to invade it successfully, and the conclusion of a peace which the people disliked, were imputed to the chancellor. Anxious to pursue a middle course, and careless of the public favour, he had gained the friendship of no party alike able and willing to support him. The Protestant dissenters disliked him as the promoter of the measures against non-conformists; the Catholics as having frustrated the king's endeavour to grant them indulgence; the Royalists as the supporter of the act of indemnity and oblivion; the populace because he had built a large house, which, it was already rumoured, was the ostentatious result of secret bribes from France or Holland. The profligate and ambitious court disliked him as a reprover of their license, and an obstacle to their advancement; and Charles, who, aided by the high-church party, might have supported him against these assailants, had recently entertained a fresh ground of dislike. He knew that Clarendon opposed his infamous plan of obtaining a divorce; and he believed him to have promoted the marriage of Miss Stewart, whom, after obtaining such divorce, Charles had intended to espouse. The discontented nation clamoured for a victim; and the ungrateful king was glad to sacrifice to popular vengeance the minister whose stubborn honesty was opposed to the gratification of his will. He sent a message to Clarendon, then in affliction from the recent death of his wife, advising him to resign, with a view of saving himself from impeachment. Clarendon refused to take so humiliating a step; and Charles deprived him of the great seal on the 13th of August 1667. Clarendon, whom the impeachment preferred by Lord Bristol four years before had left unshaken, was now again exposed to this attack under circumstances which rendered it more powerful against him. Urged by the Dukes of Buckingham and Albemarle, the Commons drew up, on the 6th of November, an impeachment, consisting of seventeen articles, which, after several days' debate, was on the 12th carried up to the Lords. He was accused of designing to govern by a standing army, and advising the king to discontinue parliaments; of saying that the king was in his heart a Papist; of receiving money for illegal patents; of imprisoning in remote garrisons; of unjust sale of offices; of corruptly procuring the customs to be farmed at low rates, pretended debts to be paid by the king, and the company of vintners to obtain undue advantages; of procuring grants to be made to himself and his relations; of introducing arbitrary government in the colonies; of frustrating a proposal for the preservation of Nevis and St Christopher's; of advising and effecting the sale of Dunkirk; of unduly causing the king's letters-patent to Dr Croucher to be altered; of arbitrary conduct in the council; of having caused *quo warrantos* to be issued against corporations, with the intent of extorting money; of having corruptly procured the bill of settlement for Ireland; of having deceived the king in his administration of foreign affairs, and betrayed his councils to the enemy; and of having counselled the division of the fleet in June 1666. To these flimsy charges Lord Clarendon replied by the mouth of his son, that if any one was proved, he would submit to the rest. His accusers were ashamed to make any one of them the specific ground of an impeachment; and accordingly he was impeached of high treason in general terms, and his imprisonment demanded, until the Commons, "in convenient time," shall exhibit "articles against him." The Lords refused to imprison him on this general accusation. Much controversy ensued between the two houses, during which, in compliance with the entreaties of his friends, and the intimated wishes of the king, Clarendon closed the dispute by withdrawing himself from the kingdom on the 29th of November 1667, and retiring to France. He left on his departure a vindication of his conduct, addressed to the House of Lords, which address was communicated to the Commons, by whom it was voted that it was scandalous and seditious, and should be burned by the hangman. The Commons then attempted to obtain his attainder, but were opposed by the Lords; and the two houses finally concurred in an act of banishment and incapacity, unless he appeared and took his trial before the 1st of February, which act was passed on the 18th of December 1667. Fresh persecutions awaited Clarendon. The court of France, in order to gain the favour of England, wished to expel him from their dominions; and it was not till their hopes of alliance were dispelled by the triple league, that they showed kindness to the distinguished exile, and Clarendon received a special permission to reside in any part of France. He abode principally at Montpellier, where, resuming his literary labours, he completed his celebrated History, and the Memoir of his own Life. From thence he re-

Hyde.

paired to Rouen, where, in the year 1674, he addressed to Charles II. a fruitless prayer for permission to spend the short remainder of his life in England. A few months afterwards he died at Rouen, on the 9th of December 1674, in the sixty-fifth year of his age.

The character of Lord Clarendon has been much exposed to undeserved extremes of praise and of censure. He has been made the idol of the high-church party, and bitterly assailed by their opponents. As a minister he appears to have been incorrupt, indefatigable, zealous for the public service, and anxious to hold an even balance between the liberties of the subject and the privileges of the crown, and to secure to the restored king only the constitutional powers of limited monarchy. His chief faults were harshness towards the non-conformists, and acquiescence in the king's clandestine acceptance of pecuniary aid from France. His merits cannot be fairly estimated, without considering the difficulties of his position, the profligacy and corruption of the times in which he lived, to which he boldly and honourably opposed himself, and comparing his administration with the disgraceful epoch by which it was succeeded. He was upright and uncompromising, and neglectful of the arts of popularity, both towards men of high and of humble station. His abilities were very great, but consisted perhaps rather in quickness than in depth and comprehensiveness of mind. He was ready and powerful as an orator, and prompt and able in the despatch of business, of which, in spite of frequent illness, he bore by far the greatest share during the period of his administration. In private life he was unimpeachable. As a writer he will ever occupy a high place. His history, as characterized by a distinguished modern historian, is "a monument of powerful ability and impressive eloquence." Its remarkable beauties are its masterly delineation of celebrated characters, the occasional eloquence of its descriptive passages, and the frequent interspersion of luminous reflections. Its chief faults are diffuseness of style, and the want of accuracy and arrangement. Its fidelity as a history cannot be upheld; a defect attributable partly to the circumstance of his having trusted much to recollection in the absence of requisite materials, partly to that desire to render it serviceable to the cause of the royalists, with which he professed to have commenced it.

His principal works are, his History of the Rebellion; A short View of the State of Ireland; and The Life of Edward Earl of Clarendon, in which is included a Continuation of his History of the Grand Rebellion. Of these three works, a complete edition, containing the passages suppressed by former editors, was published for the first time at Oxford in 1826. Brief View and Survey of the Dangerous and Pernicious Errors to Church and State in Mr Hobbes' Book entitled the Leviathan, Oxford, 1676; A Collection of Tracts, fol. London, 1727, containing, A Vindication of Himself; Reflections on several Christian Duties, Divine and Moral, by way of Essays; Contemplations and Reflections upon the Psalms of David; A Dialogue of the Want of Respect due to Age; and A Dialogue concerning Education.

(See *Life of Clarendon*, by himself, and his *History of the Rebellion;* Clarendon's *State Papers;* Wood's *Athenæ-Oxonienses;* Whitelocke's *Memorials;* Burnet's *History of his Own Times; Memoirs of James II.;* Pepys's *Diary;* Evelyn's *Diary; Parliamentary History;* and *State Trials.*) (Y. Y.)

Hyde, *Thomas*, professor of Arabic at Oxford, and one of the most learned writers of the seventeenth century, was born at Billingsley, near Bridgenorth, Shropshire, in 1636. He studied first at Cambridge, and afterwards at Oxford. Before he was eighteen years of age, he was sent from Cambridge to London to assist Mr Brian Walton in the great work of the Polyglott Bible; and about the same period he undertook to transcribe the Pentateuch out of the Hebrew characters, in which it was first printed at Constantinople, into the proper Persian characters. After he had happily succeeded in this, he assisted in correcting several parts of Mr Walton's work, for which he was perfectly qualified. "Nec prætereundus est D. Thomas Hyde," says the editor, "summæ spei juvenis, qui in linguis orientalibus supra ætatem magnos progressus fecit, quorum specimina dedit tum in Arabibus, Syriacis, Persicis corrigendo, tum in Pentateucho Persico characteribus Persicis describendo, quia antea solis Hebraicis extitit, ejusque versionem Latinam concinnando." He was made archdeacon of Gloucester, canon of Christ-church, head keeper of the Bodleian Library, and professor of Hebrew and Arabic in the university of Oxford. He was interpreter and secretary of the oriental languages during the reigns of Charles II. James II. and William III.; and he was perfectly qualified to fill this post, as he could converse in all the languages which he understood. There never was an Englishman in his situation of life who made so great progress; but his mind was so engrossed by his beloved studies, that he is said to have been but ill qualified to appear to any advantage in common conversation. This distinguished orientalist died on the 18th of February 1702. Of all his writings, the very catalogue of which is a curiosity, the most celebrated is his *Religio Veterum Persarum*, a work of profound and various erudition, and abounding with many new lights and ingenious conjectures concerning the theology, history, and learning of the eastern nations. Amongst his other works may be mentioned, 1. A Latin translation of Ulug Beig's observations on the longitude and latitude of the fixed stars; and, 2. A Catalogue of the printed books in the Bodleian Library. Dr Gregory Sharpe, master of the Temple, collected and republished some of Dr Hyde's pieces formerly printed, under the title of *Syntagma Dissertationum et Opuscula*, in 2 vols. 4to, 1767; to which is prefixed, a life of the author, containing a very judicious estimate of his labours and acquisitions. At the time of his death, Dr Hyde had planned, and partly prepared for the press, no less than thirty-one different works, some of greater and other of less importance, a list of which will be found in Chalmers's *Biographical Dictionary*, article Hyde.

HYDERABAD, an extensive province of Hindustan, in the Deccan, which is situated principally between the 16th and 19th degrees of north latitude. The name is now applied generally to all the territories of the nizam, so that it is exceedingly difficult to ascertain its exact limits. This territory composed a considerable portion of the ancient Selingana. The country is hilly, but not mountainous, being for the most part an elevated table-land, in consequence of which the climate is colder than might be expected from the latitude. During three months of the year the thermometer at the city of Hyderabad, and in the country to the north, is often as low as 45°, 40°, and even 35° of Fahrenheit. The country is fertile, and, under proper management, would yield abundantly. But the whole territory is principally rented to powerful zemindars, or is granted in jaghires to the officers of government. This distribution of the landed property, which, with the exception of some portions set aside for charitable purposes, and the estates of the nizam and the different branches of his family, is in the hands of a few individuals, is supposed to be injurious to agriculture, and of course to the interests of the revenue. The cultivators are wretchedly poor, and are much oppressed by their superiors the holders, who are subject to little or no restraint from their nominal sovereign. Where they are properly cultivated, the fields yield excellent crops of wheat, which is transported by the inland carriers to the sea-coast, whence salt is brought in return. The districts acquired by the nizam are particularly rich and fertile. But as agriculture is discouraged by the oppression of the cultivators, commerce is obstructed by heavy and injudicious internal taxes. In 1801 the custom-duties on importation amounted to 15 per cent., which formed the principal revenue of the state; and when the British remonstrated against the impolicy of these internal duties, the nizam evinced the most decided aversion to reduce them, and still more to abolish them, which was the counsel of the British government. It was at length agreed that the tax should be reduced to two and a half per cent. But even the levying of this duty was attended with such oppressions and vexation, that it greatly impeded commerce. At present, the principal trade carried on between the nizam's dominions and those under the British government, consists in the exportation of cotton to Berar and to the Northern Circars, and also to the markets at Vellore, Arnee, and the vicinity. They bring back salt and salted fish, cloths manufactured in the Northern Circars, Arnee muslins, and European manufactures; the latter principally for the supply of the British forces subsidised by the nizam, and for clothing his army. The chief towns of this kingdom are Hyderabad, Golcondah, Warangole, Aurungabad, Beder, and Ellichpore. The majority of the people are Hindus; but having been long the seat of a Mahommedan government, a considerable portion of the inhabitants are of that religion.

This country was formerly subject to the rajahs of Telingana and Bijanagur; but being afterwards conquered by the Mahommedans, was formed into a separate kingdom in the year 1512, under the name of Golcondah, by Mahommed Kooly, originally a Turkish adventurer. In 1687, it was brought under the dominion of Aurungzebe, and was converted into one of the provinces of the Mogul empire, and, with the other five southern provinces, was formed into a viceroyalty, under an officer appointed by the court of Delhi, called the soobahdar of the Deccan. In 1719, a Mogul officer, Cheen Khilij Khan, being appointed to this government, with the title of Nizam al Moolk, or superintendent of the kingdom, collected a large army, and got possession of all the strongholds of the Deccan; and setting up for independence, he overawed the emperor Mahommed Shah and his ministers. After the invasion of Nadir Shah in 1739, he left to the Mogul nothing but the name of sovereign; and having made Aurungabad his capital, he died at Boorhanpore in the year 1748, aged 104 years. He was succeeded by his second son, who was assassinated in 1750, and succeeded by his nephew Muzuffer Jung, who was assassinated the following year, and succeeded by his cousin Salabut Jung. He had been confined for ten years by his brother Nizam Ali, who for nearly twenty years was engaged in wars with Hyder Ali, the British, and the Mahrattas, during which his territories were greatly contracted. On the 12th of October 1800, he concluded a treaty offensive and defensive, by which he became a dependent and ally of the British. He agreed to receive into his territories a British force of 8000 infantry and 1000 cavalry; to relinquish to the British the management of all his foreign relations; and, for the regular payment of the troops stationed in his country, to cede certain portions of territory to the British. By a commercial treaty concluded in 1802 with the British, it was agreed, in lieu of all local duties, that a duty of five per cent. should be levied on all articles respectively imported into the territories of each. In 1804, after the conclusion of the war with Scindia and the rajah of Nagpoor, the nizam acquired a large accession of territory. At present the nizam's dominions comprehend the greater part of Berar, the whole of Hyderabad, Nandere, and Beeder, and part of Aurungabad and Bejapoor. Towards the Nagpoor territories their limits are marked by the course of the Wurda river, and on the one side of the British by the Krishna and Toombuddra. This territory may be estimated in length at 420 by 220 miles, and contains 8,000,000 of inhabitants.

Hyderabad.

Hyderabad, the capital of the above-mentioned province of Hyderabad, and of the nizam's dominions. It is situated on the south side of the Musa river, which runs rapidly during the rains, but in the dry season has scarcely two feet of water. It is said to have been founded about the year 1586 by Sultan Mahommed Kootub Shah, who, thinking the air of Golcondah did not agree with his constitution, gave orders for building a new city, which continued to be the residence of the Kootub Shah dynasty till the year 1687, when it was taken by Aurungzebe. The late Nizam Ali was the first of the nizams who made it his residence, and he spent considerable sums in improving it. It is now a large and populous place, about seven miles in circumference, and is surrounded by a stone wall, with towers at the angles and gates, which, though incapable of defence against artillery, is a good protection against the incursions of cavalry. It contains two palaces and some elegant mosques, this having long been the seat of Mahommedanism in the Deccan; and between it and Golcondah there are some handsome tombs. This city possesses large magazines, in which are deposited the presents received at various times from the different native and European powers, consisting of bales of woollen, cases of glass, glass-ware, China-ware, clocks, watches, &c. of European manufacture. These presents have accumulated during a course of seventy or eighty years, having been received by the father and grandfather of the present nizam as far back as the time of Dupleix and Bussy. Since the late Nizam Ali transferred his residence to Hyderabad, it has experienced no disturbance; and being the residence of the court, has rapidly increased in wealth and population. At present it is estimated to contain 120,000 inhabitants, including the suburbs. The travelling distance from Calcutta by the Northern Circars is 902 miles, by Nagpoor 1043 miles, from Madras 352, from Bombay 480, from Delhi 923, from Poonah 387, from Seringapatam 406. Long. 78. 42. E. Lat. 17. 15. N.

Hyderabad, a city of Hindustan, in the province of Sinde, of which it is the capital. The fortress of Hyderabad, which is appropriated solely to the residence of the princes and their families, is situated on a rock the foot of which is washed by a branch of the river Indus, here named the Fulalee. It is of an irregular pentagonal figure, suited to the natural form of the rock, and is defended by round towers, and a high brick wall perforated with loop-holes. The situation is remarkably strong; the sides of the hill being in many places so steep as to render the ascent to the fortress difficult, even though a breach were made in the walls. The weakest point is towards the south-east, opposite a break in the rock from the Fulalee. A dry ditch twelve feet broad protects the northern side. The position is good, and the fortifications adequate to resist any attack of native tooops, though it would not stand a siege of three days against Europeans. There is a good bazar and several handsome mosques within the fort; and although little encouragement is given to industry, the artisans are numerous and skilful. The Ameers, as mentioned by Dr Burnes, who went on a mission to Hyderabad in 1828, pride themselves greatly in the brilliant collection which they possess of jewels and armour. A great part of their treasure consists in rubies, diamonds, pearls, and emeralds, with which their daggers, swords, and matchlocks are adorned, and many of which they wear as rings and clasps on different parts of their dresses. The arts connected with this pursuit are encouraged by them. One or two Persian goldsmiths are engaged at court, where they work in enamel, and contrive expedients to display the jewellery of their masters. They have brought to great perfection the art of inlaying letters of gold on steel. They acknowledge the superiority of the English in the manufacture of gun-locks; and the dress of their princes and nobles consists partly of English cloths.[1] Hyderabad is situated 130 miles from the sea, on the eastern side of the main stream of the Indus, with which it is connected by the Fulalee at the distance of three miles. The country around Hyderabad rises into hills, although it is level till within a few miles of that city. The Indus is a perpetual source of fertility, affording an inexhaustible supply of water for the irrigation of the fields. The flat country of Sinde is intersected by branches from the main stream, and by canals; and the transition from the parched deserts of Cutch to such a scene of fertility is described by Dr Burnes as affording a very striking contrast. The Fulalee in the month of August is from two and a half to three fathoms deep at Hyderabad, and is covered with boats laden with heavy goods. The population is 20,000. Long. 68. 41. E. Lat. 25. 22. N.

HYDERBUNGE, a populous village of Hindustan, in the province of Lahore, dependent on Attack, and situated at a short distance from the Indus. Long. 71. 25. E. Lat. 33. 20. N.

HYDERGUR, a town of Hindustan, in the nabob of Oude's territories, thirty-two miles south-east from Lucknow. Long. 81. 23. E. Lat. 26. 37. N.

HYDERSHY, a town of Hindustan, belonging to the nizam, in the province of Hyderabad, sixty miles east from the city of Hyderabad. Long. 79. 35. E. Lat. 17. 24. N.

HYDRA, in fabulous history, a serpent in the marsh of Lerna, in Peloponnesus, represented by the poets with many heads, one of which being cut off, another immediately succeeded in its place, unless the wound was instantly cauterized. Hercules attacked this monster; and having caused Iolaus to hew down wood for flaming brands, as he cut off the heads he applied the brands to the wounds, by which means he destroyed the hydra. This hydra with many heads is said to have been only a multitude of serpents, which infested the marshes of Lerna near Mycene, and which seemed to multiply as fast as they were destroyed. Hercules, with the assistance of his companions, cleared the country of these reptiles, by burning the reeds in which they lodged.

HYDRA, in *Astronomy*, a southern constellation, consisting of a number of stars, imagined to represent a water serpent.

HYDRAGOGUES, amongst physicians, remedies which evacuate a large quantity of water in dropsies. The word is formed from ὑδωρ, *water*, and ἀγειν, *to draw* or *lead;* but the application of the term proceeds upon a mistaken supposition that every purgative had some particular humour which it would evacuate, and which could not be evacuated by any other. It is now, however, discovered that all strong purgatives will themselves prove *hydragogues*, if administered in large quantity, or to persons of weak constitutions. The principal medicines recommended as hydragogues are, the juice of elder, the root of the iris, soldanella, mechoacan, jalap, &c.

HYDRARGYRUM, a name given to mercury or quicksilver. The word is formed from ὑδωρ, *aqua*, water, and ἀργυρος, *argentum*, silver, *water of silver*, on account of its resembling liquid or melted silver.

HYDRAULICS, the science of the motion of fluids, and the construction of all kinds of machines relating thereto. See HYDRODYNAMICS.

HYDRENTEROCELE, in *Surgery*, a species of hernia, in which the intestines descend into the scrotum, together with a quantity of water.

HYDROCEPHALUS, a preternatural distension of the head by a stagnation and extravasation of the lymph, which, when collected in the inside of the cranium, is termed *internal*, as that collected on the outside is termed *external*. See MEDICINE, *Index*.
